VOL. 2—NO. 1

## RIG-BUILDER'S CIRCUIT GUIDE

Recognizing the fact that most R-F and audio circuits change very little from tube to tube, this issue presents six standard circuits. With each circuit are listed the types of tubes which will operate in that circuit, together with the circuit constants which must vary from tube to tube. These six standard circuits are therefore the equivalent of eighty-nine separate circuits.

The single tube circuits (circuits A and B) may be employed as either buffer or final circuits. An un-tuned grid circuit is shown in order to keep the diagram as simple as possible. Circuits C and D are push-pull circuits and would normally be used as circuits for final amplifiers, although low power tubes in these circuits will allow their use as buffer amplifiers. Circuit E is a class B audio modulator circuit and circuit F is a class AB<sub>2</sub> modulator circuit.

The tube operating conditions given in the tables are, in most cases, the conditions for maximum input. It is important that these limits are not exceeded. The bias voltage given in circuits A, B, C and D is designed to protect the tubes in case of excitation failure, or in case the crystal or VFO circuit is keyed. In the case of these four circuits bias is obtained by a combination of grid resistance bias and fixed bias. These values may be changed if desired. For example the grid resistor can be omitted if the fixed bias is increased. This increase in fixed bias should be equal to the amount of bias that was obtained from the grid resistor due to the grid current ( $I_g$ ). Conversely the fixed bias can be removed and the grid resistor increased to give the proper bias. This is not recommended unless the stage is protected by an overload relay in the plate circuit.

Values for grid and plate coils and condensers are not specified. Manufactured assemblies may be used, or homemade coils employed. The table gives the airgap necessary for the plate condenser. In the case of split-stator condensers, the airgap given is still valid for each section. This value of spacing allows a 100 per cent factor of safety.

Neutralizing condensers (NC) should have an airgap 50 per cent greater than that of the plate condenser. Maximum usable capacity of the neutralizing condenser should be somewhat greater than the grid to plate capacitance of the tube it is used with.

The wattage of the various resistors is not given. This is easily computed by  $I^2R$ , where I is the current through the resistor (grid current or screen current). Use a wattage rating which is approximately double the computed value, as a safety factor.

### CIRCUIT A

The filament bypass condensers may be of the 600 volt paper type. The 0.001 mf plate bypass condenser should have a voltage rating of twice the d-c voltage for c-w operation and three to four times the d-c voltage for phone operation. The r-f choke should be of the all-band type and be capable of handling the d-c plate current.

### CIRCUIT B

The circuit as shown is for phone operation only. If c-w operation is desired, omit resistor  $R_2$ , and use a

separate source of voltage on the screen grid as indicated in the table. Circuit B is used for tetrodes, beam power tubes, and pentodes. If the beam-forming plates of the beam tubes are brought out to a pin connection, they should be connected to the center-tap of the filament transformer. If the tube has a cathode connection, it should be connected to ground. The suppressor grid in pentodes should also be grounded, unless the table indicates that a positive voltage is required. In the latter case a well-regulated source such as a battery should be used.

The filament bypass condensers may be of the 600 volt paper type. The 0.002 mf plate bypass condenser should have a working voltage of twice the d-c voltage for c-w operation and three to four times the d-c voltage for phone operation. The screen bypass condenser (0.005 mf) should be rated at twice the screen voltage for c-w work and three to four times the screen voltage for phone operation.

### CIRCUIT C

This circuit is the push-pull version of circuit A. The same comments apply regarding bypass condensers. In addition, the 0.01 mf grid circuit bypass condenser may be a 600 volt paper condenser for most circuits, unless the bias voltage is very high, in which case a 1250 or 2500 volt mica is preferable.

### CIRCUIT D

Push-pull tetrodes, beam power tubes or pentodes may be used in this circuit. As in the case with circuit B, the diagram shown is for phone operation only. For c-w operation remove  $R_2$  and supply screen voltage from a separate source. All remarks regarding beam-forming plates, cathodes and suppressor grids pertaining to circuit B also apply to circuit D. Similarly, the comments on bypass condensers also apply.

### CIRCUIT E

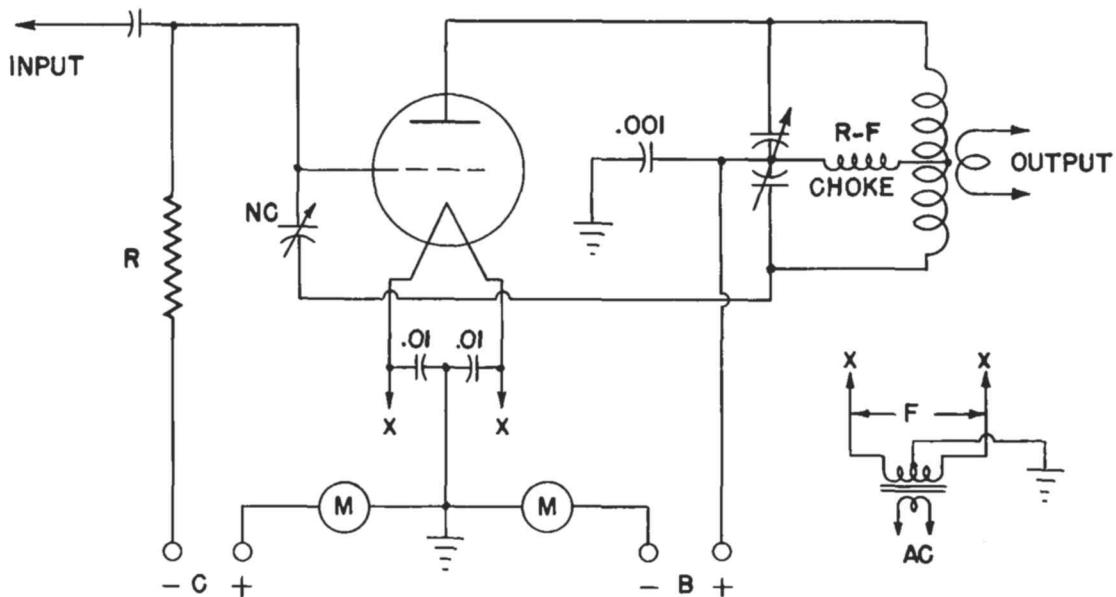

This class B modulator circuit is quite straightforward. The table gives complete operating data, including output impedance, plate-to-plate. Grid bias requirements are small, so that batteries may be used in most cases. Two tubes, the GL-811 and the GL-838, are zero bias tubes. In this case the C- and C+ terminals may be tied together.

### CIRCUIT F

Tetrodes, beam tubes or pentodes may be used as class AB<sub>2</sub> modulators in this circuit. Both transmitting tubes and receiving tubes are included in the table. Beam tubes with an external connection for the beam-forming plates should be used with the beam-forming plates tied to the center tap of the filament transformer. Tubes with cathodes should have the cathode grounded, and pentodes should have their suppressor grid grounded unless the table indicates otherwise.

It is necessary to use a well-regulated source of voltage for the screen-grid supply (+SG). For this reason a separate power supply is recommended. It is possible to use a voltage divider circuit, but the screen current varies so much in operation that the divider must draw a current equal to the screen-grid current. The divider is thus not economical.
