Dependability and long life previously available only in high-cost relays...

G-V
RED/LINE
low-cost thermal timing relays

The sound design, sturdy construction and reliable operation long associated with G-V Hermetically Sealed Thermal Relays is available in a low-cost form, fully qualified for industrial control...light and inexpensive enough for electronic and communications circuits.

Delays of 2 seconds to 3 minutes • Energizing voltages - 6.3 to 230 AC or DC.

- RUGGED STAINLESS STEEL MECHANISM
  Relay mechanism is of stainless steel, differential expansion type, used in all G-V Thermal Relays. All parts are welded into a single integral structure.

- SHATTERPROOF—NO GLASS
  No glass is used in mechanism, encasing shell, or base. This avoids the danger of cracking or breakage in handling and use.

- STEEL ENCASED HEATERS
  Heating elements are conservatively designed, wound with Ni-chrome wire on mica and encased in stainless steel, insuring long heater life even when energized continuously.

- DUST TIGHT ENCLOSURE
  A dust tight metal shell completely enclosing the relay mechanism and contacts, crimped tightly to the base, provides complete protection for the structure.

- TAMPER PROOF
  Time delay intervals are preset at the factory. Thus changes of delay interval in the field which might damage associated equipment are avoided.

- DIRECTLY INTERCHANGEABLE
  Directly interchangeable with all other octal-size relays.

Exploiting Thermistors
In ELECTRONIC DESIGN

This is our third issue this month. The “extra” edition permits us space to bring you a special feature section devoted entirely to thermistors. Thermistors have been around for quite some time, but we expect you’ll be working with them more in the near future. We expect units will be available with closer tolerances at no increase in cost.

A deterrent to the wholesale use of thermistors has been the wide tolerance to which they were made. It has been difficult to match a thermistor to a transistor to compensate for temperature change (some people will certainly take exception to this statement, but as a generalization there has to be much hand work in making or picking thermistors). There has been no specification on thermistors which a customer could specify to insure a constant quality. The “Specifying Military Thermistors” by Bernard Schwartz of RCA, page 34 should prove a helpful guide to the inexperienced buyer.

In gathering material for this issue, we are deeply appreciative of the efforts made by thermistor manufacturers to supply us with information that would be most helpful to designers. An abundance of design information exists in the manuals and data books put out by manufacturers. We have not warmed this over, but bring instead new approaches to designing with thermistors. More new design articles will appear in succeeding issues. We think you’ll particularly appreciate Mr. Schwartz’s design aids which boil the problem down to using curves and nomograms.

Thermistors can be used in the following applications: temperature measurement, temperature compensation, temperature control, liquid level gauges, time delays, surge suppression, switching, microwave power measurement, volume limiting, voltage regulation, compressors and expanders, age, overload protection, and oscillator amplitude stabilization. If you’re not now using thermistors, you ought to look into them. If you’ve found them inadequate in the past, watch future developments closely.

Do your transistors have temperature problems?
...solve them with Globar thermistors

Minimize Ico variation and prevent thermal runaway by using Globar thermistors. They are available in a wide range of resistance values and temperature coefficients to meet most transistor circuit requirements.

Globar Thermistor Test Kits are available for general evaluation in transistor circuits. If you have a specific transistor temperature problem, submit details to GLOBAR Plant, The CARBORUNDUM Company, Dept. ED 87-711, Niagara Falls, New York. Ask for Technical Bulletin GR-3... describes physical and electrical characteristics of GLOBAR Thermistors.

Globar Ceramic Resistors

NEW—Raytheon Amplitron
Now—peak power 800 kw, bandwidths of 10%
with efficiencies of 50-70% over entire band

The Amplitron is a new type of tube capable of power amplification at microwave frequencies. Amplification is obtained over a broad range of frequencies without need of mechanical or electrical adjustments. The Amplitron is a derivative of the magnetron and retains many of its advantages—high operating efficiency, simple construction, small size, light weight, low operating voltage.

The Amplitron uses crossed electric and magnetic fields, a reentrant beam produced by a magnetron-type cathode, and a non-reentrant broadband circuit matched at either end to external circuits.

Variations in anode current or voltage have little effect upon the total phase shift. This results in very low phase shifting and excellent reproduction of the input spectrum even under pulse conditions with slow rise time and ripple. Because of low insertion loss, duplexing may be accomplished at the input rather than the output of the final rf amplifier.

A limited quantity of preliminary literature is now available. To be sure of your copy, write now. Amplitrons in other frequency bands are currently in development. Inquiries are invited.

Constant-Current Varistor Announced

A field effect varistor with a constant current feature has been announced by Bell Telephone Laboratories, New York City. The two-terminal passive semiconductor component is applicable as a current regulator where load or supply varies over 20 to 120 v.

Still in the experimental stage, the component has other applications as a current limiter or as a pulse shaper; with its low impedance, it can be used as a coupling choke or ac switch.

The field effect varistor is related to the field effect transistor. A single planar junction is made by diffusion. Current passing parallel through this junction goes through a constricted channel. As the voltage increases, the current increase and a depletion layer builds up to the entire thickness of the channel. At a "pinch-off" point, voltage increase does not produce any current increase. Before an avalanche breakdown point, and after the pinch-off point, current is essentially constant—and this is the region of primary interest.

For more information on developments described, write directly to the address given in the individual items.
Coded TV Pictures

Techniques for improving the efficiency of long-distance television picture transmission were revealed by the Technicolor Corp., Burbank, Calif. Bandwidth reductions of as much as 4 to 1 were reported. In the complete system a normal television camera output is fed into a high-speed electronic computer which codes the video signal into a series of dots and spaces as in the Morse code before transmission to the receiver. There a similar computer translates the code before presenting the picture on a television tube. An essential feature of the device is the temporary retention of the coded signal in electrostatic storage tubes to average out the information rate. Laboratory equipment built so far handles pictures with just two levels of brightness, but additional circuitry to permit acceptance of a complete tone scale is approaching completion and will yield the same bandwidth reduction factor. Color TV signals may also be transmitted with only slightly greater bandwidth than for black and white pictures.
AMPLIFIERS

Wide band, fast pulse amplifiers — 90 db in cascade — distortion-free amplification of pulses shorter than 0.01 μsec!

At moderate cost, -hp- 460A and 460B Amplifiers offer true amplification of millimicrosecond pulses at power levels sufficient to operate scalers, counting meters and cathode ray tubes.

Model 460A provides voltage gain of approximately 20 db while Model 460B is a 15 db terminal amplifier insuring maximum output. Since rise time is 0.0026 μsec, and overshoot and ringing are negligible, distortion-free amplification of pulses faster than 0.01 μsec is assured. The high gain, no distortion feature means the instruments, in cascade, serve as a 100 MC pre-amplifier for standard oscilloscopes, and a x 10 sensitivity multiplier for voltmeters. Rack mount model only. -hp- 460AR, $185.00. -hp- 460BR, $225.00.

General purpose amplifier — 20 or 40 db gain — high stability 10 cps to 1 MC — low priced at $140.00

-hp- 450A is an ideal, general duty amplifier for use wherever wide frequency coverage and stable gain are desired. Gain is 40 ± ½ db or 20 ± ½ db at 1,000 cps as selected at front panel switch. Frequency response is flat, stability is ±2% on ± 10 volt changes in line power, input impedance is 1 megohm with approximately 15 μF shunt, distortion is less than 1%, output 10 volts maximum into 3,000 ohms. The instrument is resistance-coupled and has no peaking or compensating networks. Phase shift is negligible and there are no spurious resonances or oscillations. Hum is minimized by a dc filament supply to the two amplifier tubes. $140.00.

Data subject to change without notice.
Prices f.o.b. factory

-hp- also offers 4 Traveling-Wave Tube Amplifiers covering frequencies 2 to 12.4 KMC! See your -hp- representative or write direct for details!

ENGINEERING REVIEW

Mach 2 Bomber Control System Disclosed

The autopilot and flight control system that makes it possible to fly a Mach 2 bomber was revealed by the Eclipse-Pioneer Division of Bendix Aviation Corp., Teterboro, N.J.

The Convair B-58 Hustler control system continuously senses and computes maximum control-surface movement permitted by the structural limitations of the supersonic jet over its entire range of speed. The control system also takes into account the constantly changing atmospheric conditions the plane encounters. In effect, the human pilot is prevented from putting the plane into any maneuver that could instantly destroy it.

Sensing units in the nose of the delta-wing jet pick up data on the plane's air environment—air speed, temperature, air density, and other vital information. This information is evaluated and compared in a central air data computer. Appropriate control information from the computer is then relayed through an amplifier computer to a complex electromechanical device, the power control linkage assembly (PCLA).

In the PCLA the pilot's control-stick movements are translated into correct control-surface action by the power control part of the system. This control-surface action varies from a 20 deg movement under one set of conditions to eight-tenths of one degree under extreme-opposite conditions of speed and air environment. Yet, there is no difference in the "feel" of the controls, as far as the pilot is concerned, between the two

Control signals from the pilot or automatic guidance system of the Convair B-58 Hustler, pass through the power-control linkage assembly. This 267-pound electromechanical device, which contains an array of 17,000 parts, translates into linear motion, electronic signals from a computing system that senses aerodynamic forces.

In addition, the PCLA computer receives

Avon L-162

This 50-ton B-58 is the latest, and the largest, to-be-factory built. It is the first of a new class of jet bombers, and delivery date is early in 1960.

Control signals from the pilot's control-stick movements are compared with those from the autopilot and the guidance system, and a directional difference is computed by the computer. This difference is used to compute the necessary control surface movement of the jet.

The computer's output is in the form of a voltage signal, which is used to control the power amplifier to produce a control-surface movement. The power amplifier is a high-speed amplifier that can produce 40 deg of movement in one second.

extremes. The B-58 power control system can develop a maximum torque of 120 ton-foot.

Designed into this control system is a process called “mixing.” The conventional airplane has both elevators for up or down movement and ailerons for banking. The delta-wing Hustler, however, has just one set of control surfaces, elevators, which “mixes” the work of both elevators and ailerons.

Automatic Missile Launcher

This is a prototype of the automatic missile loading and launching equipment for firing a series of ground-to-air defense missiles of the Talos type. Designed and built by American Machine & Foundry Co., 261 Madison Ave., New York, N.Y., the equipment has been delivered to White Sands Proving Ground, New Mexico, where it is installed in the Talos Defense Unit.

On command from computers in the control station, the launcher turns toward the cell in the circular storage magazine which contains the desired type of missile for the tactical mission. A cart runs out to the automatically preselected cell, picks up a missile and returns to the launcher. The missile is then positioned in the launcher where it is elevated and rotated to firing position. When the firing signal is received, the missile is fired automatically and the launcher recycles for the next round. Unloading is also automatic.

In Case You Wondered—
HSD—Hoffman Electronics Corp.

We're sorry, too, that the following Hoffman types were not listed: IN465; IN466; IN467; IN468; IN469; and IN470. These types span the zener voltage range of 2.0 to 8.0 volts at I_z = 5 ma dc.

LEACH balanced-armature relays solve environmental problems

...unique design gives high resistance to shock, acceleration, vibration

Leach Balanced Armature relays are now solving the most exacting problems for systems designers. Exclusive balanced armature design eliminates faulty operation of contacts due to vibration and shock forces. Bifurcated contacts assure high reliability in contact-making circuits. You'll find these exceptional relays give optimum performance in resistance to shock, acceleration and vibration.

Typical Ratings

6 P.D.T.
Normal operating voltages—6-115 vdc—115 vac (400 cycle).
Contact ratings @ 28 vdc or 115 vac, single phase
Resistive—3 amp @ 125°C
—5 amp @ 85°C (dc only)
Inductive—1.5 amp @ 85°-125°C
Motor Load—1.5 amp @ 85°-125°C
Rated duty—continuous
Minimum cycles—100,000
Weight—0.3 lbs. max.
Shock—50 G's
Vibration—15G's—5000 cps
Applicable specifications
MIL-R-6106C
Class A5, A8, B8
Minimum current test applicable
MIL-R-5757B
Class A & B

We invite other special requirements such as microamp switching, high vibration, and special mounting.

Designers who look to Nylon look to NATIONAL first

For fabricated parts—or for extruded strip, rod, tubing or special shapes—you'll find National a dependable primary source of Nylon. Costly molds and time delays may favor the delivery of 100% usable parts fabricated from National Nylon and timed to your production needs.

In many cases, fabricated parts from standard or special extruded shapes give you more design freedom at no greater unit cost. Buying from the source makes this possible. Before you "freeze" a molded design, talk with your National Sales Representative.

Check him, also, for your other basic materials needs—PHENOLITE® Laminated Plastic, Vulcanized Fibre, PHENOLITE Copper-clad. Many grades from the more than 100 available—including Nylon rod—are "in stock" for immediate shipment. For Nylon sizes, grades and properties, write Dept. E-4 for our Technical Data Folder.

ENGINEERING REVIEW

Electrical Cable Guides Car

An automobile automatically steered by an electrical cable beneath a concrete surface cruised along a one-mile check road.

During the demonstration held at General Motors, Warren, Mich., the car rolled along the two-lane road and negotiated the banked turnaround loops at either end without the driver's hand on the steering wheel. To turn off the road or pass another vehicle, the driver switched back to manual steering.

Guidance was accomplished by a circular magnetic field created by the low frequency ac line. A pair of tuned pickup coils on the front bumper of the vehicle straddled the field. Any deviation or lateral motion of the car produced a difference in voltage from one pickup coil to the other. These voltage variations were fed into a small analog computer on the instrument panel. The computer was linked with a servo system that controlled the modified power steering unit.

The computer transmitted command signals to the servo mechanism which positioned the front wheels. Thus, if the car underwent any deviations from its straight-ahead course the automatic steering system brought it back into the straight-ahead path.

Flammability Testing of Laminates

A flammability test unit is aiding research and development programs on flame-retardant laminates. Installed recently at Continental Diamond Corp., Bridgeport, Pa., test equipment provides detailed and specific information on flammability characteristics.

The specimen is placed within the unit's heating coil, which can heat the specimen to temperatures in excess of 860 C. Specially designed electrodes located immediately adjacent to the test specimen emit a constant stream of high-voltage sparks which ignite the gases arising from the heated specimen. After a burning period of 30 sec, all current is cut from the heating coil and spark electrodes, following which the time required for the flame to extinguish itself is measured.

**NEW METAL GRID**

### ALLEN-BRADLEY PRESENTS...

$\frac{1}{4}$, $\frac{1}{2}$, and 1-WATT PRECISION RESISTORS

**Far exceed MIL Specs for film and wire-wound resistors**

Allen-Bradley's new, truly accurate, metal grid resistors are now available in $\frac{1}{4}$, $\frac{1}{2}$, and 1-watt ratings, producing test results that are a substantial improvement over the MIL Specifications for wire-wound and film type precision resistors. They combine remarkable stability, under load and on the shelf, with an exceptionally low temperature coefficient. The metal alloy grid is noninductive, providing excellent high frequency characteristics. They also have an exceptionally low noise level...comparable to that of wire-wound units. Each unit is individually calibrated and marked with nominal resistance value, tolerance ($\pm 0.1$ to $1\%$), and temperature coefficient. Provided with gold plated leads for flawless soldering. Considering their superior characteristics, these new resistors justly qualify under the Allen-Bradley trademark of Quality.

**Type GAH**

$1$ Watt at $100^\circ$C

$\pm 0.1$ to $1\%$

The construction of the $\frac{1}{4}$, $\frac{1}{2}$, and 1-watt resistors is identical. At the upper left is an enlarged view of the metal alloy grid, mounted on glass, which forms the resistance element. (A) Actual size of 1-watt element, (B) encapsulating epoxy resin body, (C) finished unit hermetically sealed in ceramic tube.

General Electric Co.  
Edmore, Mich.

THE THERMISTOR, born some two decades ago in the laboratories of Western Electric, is now assuming full stature as a design component. Its unusual properties—extreme sensitivity, negative temperature coefficient, and high reliability make it an ideal component for modern electronic equipment. It is only in the last few years that manufacturers have taken up the challenge of providing the design engineer with reliable, standard, thermistor types. The versatility of thermistors is already reflected in a wide variety of applications, from medical temperature probes to missile-fuel sensing elements. Temperature measurement and control for instrumentation has become a major area of thermistor use.

The use of thermistors in transistor circuitry should prove of the greatest interest to designers. Thermistors are a good design choice for compensating transistor-circuits because they are of extremely small size, are very sensitive to temperature change, have indefinite life, are economical, and have very stable and reproducible characteristics within their design limits.

Active research is still being carried on and new thermistor types are being developed, such as special bolometer thermistors and ultra-low temperature thermistors. Research is also increasing the accuracy and reproducibility of thermistor types. Most present manufacture is still on the batch system, and continuous controlled production is an important goal. The evolution of a complete set of standard thermistor types is making the thermistor an invaluable tool for the designer.
WHILE the thermistor is not a new product, nor even a new development, its commercial history is comparatively recent. With the increasing demand for small rugged components like the thermistor, that fit the growing technical complexity of circuits, some planning for the future was a necessity. In the summer of 1957, as a result, an extensive market survey was carried out by the General Electric Co.

For clarification, and for better visualization of types of applications, we might indicate subdivisions of typical applications of the three major branches:

**Temperature compensation**

Fluctuation in temperature will often affect many electrical and electronic systems or components, reflecting undesirable changes in resistance and general operating characteristics. In most cases a thermistor incorporated properly in the circuit will compensate for the expected temperature change. Some of the typical applications of this type of thermistor are:

- Vertical deflection yoke on 110 degree television cathode-ray tubes.
- Transistors and associated circuitry.
- Fuel flow, in relation to ambient temperature fluctuations in a fuel injection system.
- Delicate miniature or subminiature instrumentation, servomechanisms, missile components, or relays.

**Temperature measurement and control**

Thermistors have a high temperature coefficient of resistance, and can be effectively used to measure and control reasonable changes in temperature. With high resistance in a small mass, both rapid and accurate measurements are easy to obtain, even when the thermistor itself is spotted remotely from the measuring circuit. Some typical applications:

- Indication of engine oil or water temperatures.
- Oven roast-food probe.
- Electric range surface and oven controls.
- Indoor/outdoor temperature controls for home and industrial heating systems.
- Indication and control of temperature in chemical reaction stills, kettles, or other industrial apparatus.
- Replacement of thermocouples for temperatures ranging up to 400 C.

**Time delay and inrush surge suppression**

The thermistor's inherent thermal inertia delays current-rise through it, and through its associated circuitry. A thermistor prevents a large initial current surge caused by application of voltage to cold electrical components such as relays, tubes, transformers, or motors. Typical applications are:

- Protection for longer life of TV and radio tubes by limitation of inrush currents.
- Time delays required for many electrical or mechanical devices; one of these worth mentioning is the steadily growing adoption of home and industrial air-conditioning.

Major producers found it difficult to assess either present quantitative demand for thermistors or parameters for future potential. To efficiently predict trends or usage, and consequent effect upon production facilities, it was necessary to definitely determine the real areas of market growth.

To provide complete coverage, the survey was divided into two separate sections—a series of personal interviews and a direct-mail questionnaire. Based upon various informational sources, it is estimated that at least one-quarter of the total industry market was covered by the man-to-man interviews. Of the mailed question sheets, about 23 percent were filled out and returned to the checking source. Results of both surveys closely agreed, and it is felt that the voluminous data eventually compiled represents a good sampling of the thermistor market.

Over an extended period, based on final study of the paired surveys, the total industry market for all types of thermistors should be something like this:

<table>
<thead>
<tr>
<th>Year</th>
<th>Market Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1958</td>
<td>$3,000,000</td>
</tr>
<tr>
<td>1959</td>
<td>$3,500,000</td>
</tr>
<tr>
<td>1960</td>
<td>$5,000,000</td>
</tr>
<tr>
<td>1961</td>
<td>$6,500,000</td>
</tr>
<tr>
<td>1962</td>
<td>$7,500,000</td>
</tr>
<tr>
<td>1965</td>
<td>$9,000,000</td>
</tr>
</tbody>
</table>

These figures do not include "captive" industrial production.

Breaking down these totals into thermistor application areas, both for the known present and the expected future, we may expect:
New Silicon Rod for Transistor Research

Sylvania casts Silicon in new smaller diameters to save engineering time

Cast silicon rod in diameters ranging from 4 mm to 15 mm and lengths from 1 inch to 18 inches is now available from Sylvania, leading source for semiconductor materials. In this new form Sylvania silicon is ready for floating zone purification without further processing. Laboratory analysis and experimentation are accomplished with greater speed and convenience.

Rods are polycrystalline, high in purity and have a density near theoretical. They are available in three standard grades based on resistivity—from solar grade to over 100 ohm cm p-type or 40 ohm cm n-type. Sylvania silicon is available also as polycrystalline, stalagmitic rod 1½ inches in diameter.

Sylvania supplies n-type germanium in the form of undoped single crystals and polycrystalline as-reduced or purified ingots. Resistivity of the purified material is greater than 40 ohm cm at 25°C. Both silicon and germanium are available in specially cut pieces to fit practically every type of crucible or boat for crystal growing.

Contact Sylvania's Chemical and Metallurgical Division for further information on the new small diameter cast silicon rods and other semiconductor materials.

Although in ratio the various types of uses may be expected to vary by 1965, its dollar value will increase as indicated in earlier pages. Although certain applications may narrow or widen, overall usage will grow. It may be of some interest to chart—using the survey results—some places where thermistors may be more broadly adopted than at the present time.

Temperature compensation

In general, both mechanical and electrical devices will tend to become more remotely operated and controlled, and also more automatic. In case of the military missile, more exact control is mandatory over wider temperature ranges. In these applications, certainly, the thermistor will be more frequently used, and more as a part of a planned system than as an individual item.

Temperature measurement and control

It is confidently expected that there will be extension of the effective temperature range of the thermistor. This will lead to a more simplified measurement of temperature, especially in remote locations.

Time, as a measurement of how food should be properly cooked, is being discarded in favor of using food temperature as a criterion. Already the thermistor is in use in this field, and recent design trends forecast an increasing growth.

Rigid control of home or industrial heating units, using thermistors, will provide a more uniform temperature. Individual-room control can be obtained, a special role for the thermistor.

Time delay, and initial-surge suppression

There is a large field for the thermistor in the protection of elaborate industrial lighting systems large inrush current. From a dollar viewpoint, this will increase lamp life and will reduce costly maintenance schedules.

Thermistors will be more widely used as a safeguard against faulty or erratic operation of relays or other control devices due to spurious currents.

As previously mentioned, the growing use of air-conditioning units, both domestic and industrial, will compound the problems of the utility companies. Initial inrush current to electric motors and sudden peak demand can be controlled by the thermistor. Of this last item, air-conditioning is only one of the fast-growing appliances that are appearing in the field of power consumption.

The potential of this thermistor application prob-
HIGH-PLUS OR LOW-MINUS TEMPERATURES

CAN'T TROUBLE HEINEMANN CIRCUIT BREAKER RATINGS

set trip points never vary with ambient conditions

The current rating, minimum and must-trip points of a Heinemann circuit breaker are accurate, reliable and always constant values. They never require compensation for ambient heat or cold.

The reason why is a simple one: hydraulic-magnetic actuation.

The Heinemann hydraulic-magnetic circuit breaker measures the actual amount of current passing through the sensing coil. Not the heat generated by that current, but the current, or amperage, itself.

That's why the Heinemann circuit breaker will always carry full, rated capacity . . . will always trip as specified. No need for de-rating tables, graphs, or mathematical computations. Nothing left to chance.

Heinemann circuit breakers are available to your specs in just about any permanent rating you want between 0.010 and 100 amperes. With a choice of time-delay characteristics, too.

This fresh approach to the design of thermistor temperature-compensating networks develops a simple three-step solution to network problems. The use of normalized curves and nomograms save laborious calculations. Curves and nomograms for two-resistor networks will be presented in a succeeding article.

Quick Design of Thermistor Compensation Networks

Bernard R. Schwartz
Radio Corp. of America
Defense Electronic Products
Camden, N. J.

The USE of temperature compensating networks having thermistors as the active element has been steadily increasing the last few years. Among the many circuit applications which utilize such networks are those where transistors, deflection yokes, meters, and other components are to be exposed over a wide ambient temperature range. Other articles have indicated methods for the solution of these networks graphically (Refs. 1, 2) and for compensating copper-wound components (Ref. 3).

The approach taken here is that the designer has already made suitable tests to determine the resistance-temperature characteristic required. By selecting the desired performance from normalized temperature characteristic curves, a rapid solution of the circuit values is possible.

Temperature compensating networks (see Table I) involving one or two additional resistors together with a thermistor have been investigated. (Curves and nomograms for two-resistor networks will be presented in a succeeding article.) It was assumed that the resistors were temperature passive compared with the thermistor, which exhibits a negative temperature characteristic approximated by:

\[ r_t = r_{t25} \exp\left(-\frac{1}{T_t} - \frac{1}{298}\right) \]  

(1)

The solution of circuit equations using the indicated nomenclature is as follows:

Type I(a)

\[ R_i = \frac{R_t r_t}{R_t + r_t} \]  

(2)

\[ F = \frac{R_t}{R_{t25}} = \frac{r_t (R_t + r_{t25})}{r_{t25} (R_t + r_t)} = f\left(\frac{k_1 + 1}{k_1 + f}\right) \]  

(3)

Type I(b)

\[ R_i = R_2 + r_t \]  

(4)

\[ F = \frac{R_t}{R_{t25}} = \frac{r_t (R_2 + r_{t25})}{r_{t25} (R_t + r_t)} = \frac{k_2 + f}{k_2 + 1} \]  

(5)

Type II(a)

\[ R_i = \frac{R_3 (R_2 + r_t)}{R_3 + R_2 + r_t} \]  

(6)

Type II(b)

\[ R_i = \frac{R_4 (R_3 + r_t)}{R_4 + R_3 + r_t} \]  

(7)

\[ F = \frac{R_t}{R_{t25}} = \frac{r_t (R_4 + r_{t25})}{r_{t25} (R_t + r_t)} = \frac{k_4 (k_3 + f) + k_3 f}{k_4 (k_3 + 1) + k_3} \]  

(8)

These equations can be solved for \( F \) by the substitution of appropriate values for \( f, k_1, k_2, k_3 \) and \( k_4 \). The following \( "k" \) values were substituted for individual calculations: 0.01, 0.02, 0.05, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10, 20, and 50.

The values of \("f" \) used in these equations correspond to the resistance-temperature response of a specific thermistor material. Table II shows the various normalized values for this constant. Material \( f_1 \) was chosen as being the fastest response material available from most, if not all, of the thermistor sources. (Full sets of curves for another material, \( f_2 \), are not included in this article since such thermistors are available from only one manufacturer.)

The use of other materials for similar calculations would only require that their normalized
temperature response values be inserted in the equations. Little variation in the network temperature response was noticed for the different thermistor materials, especially for the Type II circuits. Apparently the temperature-passive resistors so completely modify the thermistor's response that only extreme differences between thermistors can display significantly different network responses.

Procedure

The designer selects the normalized dc resistance temperature response he desires from the various graphs. A particular curve is selected and the value of the "k" constant(s) noted. Interpolation between plotted curves is possible. With the noted "k" value(s), the appropriate nomogram quickly permits determination of the ohmic value(s) of the resistor(s) and the thermistor at 25 °C. Note that the nomogram's scale for network resistance value at 25 °C has a multiplier at 10x. The appropriate value of the thermistor's resistance would then be scaled by the same 10x multiplier.

Example No. 1

A network is desired which has the following resistance-temperature response:

Step 1:

The network resistance value variation is then normalized with respect to the 25 °C value.

<table>
<thead>
<tr>
<th>Resistance (ohms)</th>
<th>Temp. (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>15,000</td>
<td>-40</td>
</tr>
<tr>
<td>13,200</td>
<td>-20</td>
</tr>
<tr>
<td>10,800</td>
<td>0</td>
</tr>
<tr>
<td>9,000</td>
<td>10</td>
</tr>
<tr>
<td>6,000</td>
<td>25</td>
</tr>
<tr>
<td>3,900</td>
<td>40</td>
</tr>
<tr>
<td>2,400</td>
<td>50</td>
</tr>
<tr>
<td>1,380</td>
<td>65</td>
</tr>
</tbody>
</table>

Step 2:

An examination of the above table shows:

a. the required network should be fairly stabilized at the lower temperatures;
b. the required network continues to drop rapidly at temperatures near the high end of the temperature range.

These characteristics are indicative of shunt networks (see Figs. 1 and 2). Series networks (see Figs. 4 and 5) have characteristics which change.
rapidly or are relatively stable at the opposite extremes of this temperature range.

An examination of Figs. 1 and 2 will show that Fig. 2 has curves which more closely approximate the desired performance. If \( k_1 = 2 \) is chosen the actual curve will be slightly higher at temperatures below 25 °C. If an interpolation of \( k_1 = 1.5 \) is attempted, the fit of the actual curve to the required curve will be better over the entire temperature range.

With no other application data available, this latter choice is made. When the interpolated curve of \( k_1 = 1.5 \) is used the following network performance is indicated:

\[
\begin{array}{c|c}
 F & \text{Temp. (°C)} \\
 2.4 & -40 \\
 2.2 & -20 \\
 1.78 & 0 \\
 1.44 & 10 \\
 0.62 & 40 \\
 0.44 & 50 \\
 0.255 & 65 \\
\end{array}
\]

**Step 3:**

The appropriate nomogram for the shunt network is Fig. 3. A straight line is then drawn between the 1.5 point on the \( k_1 \) scale and the 6 on the network resistance value scale. This line intersects the thermistor resistance value scale at 10. Since the network scale is in thousands the same multiplier is used for the thermistor value scale. Thus, \( R_n \) is equal to 1.5 times 10,000 or 15,000 ohms. The circuit appears as:

**Example No. 2**

A network is desired with the following resistance-temperature response within 5 per cent:

<table>
<thead>
<tr>
<th>Resistance (ohms)</th>
<th>Temp. (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>19,500</td>
<td>-55</td>
</tr>
<tr>
<td>18,900</td>
<td>-25</td>
</tr>
<tr>
<td>18,500</td>
<td>0</td>
</tr>
<tr>
<td>16,000</td>
<td>25</td>
</tr>
<tr>
<td>11,100</td>
<td>50</td>
</tr>
<tr>
<td>7,700</td>
<td>80</td>
</tr>
</tbody>
</table>

**Step 1:**

Variation of network resistance value is first normalized with respect to its 25 °C value:

**Step 2:**

A brief examination of the above table shows that the desired response:

a. does not change rapidly at temperature excursions below room ambient, and

b. does fall rapidly between 50 °C and 80 °C.

An examination of the Fig. 1 shows that type 1(a) circuits show this general trend, while type 1(b) circuits, Fig. 4 show the opposite. That is, they tend to display rapid increases with temperature excursions below room ambient and do not fall rapidly at temperatures above room ambient.

Fig. 1 shows a curve having markedly similar response to the required one when \( k_1 = 0.2 \).

For \( k_1 = 0.2 \), the following network values are obtained: (These values meet the tolerance of the required response).

Thermistor Data Chart

Representative groups of thermistors made by major manufacturers are tabulated here. These are standard catalog items. Most manufacturers also produce special thermistors to customer specifications. Not included are the various thermistor assemblies produced for specific applications such as microwave power measurements, etc. Characteristics included in the table are described below.

Cold Resistance

The cold resistance, $R_c$, is the resistance value of a thermistor at a specified temperature when measured with zero electrical power dissipated in it. (For practical purposes, the resistance of thermistors is measured with test current sufficiently small to limit the rise in temperature of the unit to less than 0.01 °C above test temperature.)

Dissipation Constant

The dissipation constant, $b$, is a constant of proportionality between the power dissipated and the resultant temperature rise in a thermistor at a specified temperature. Practically, this constant is the number of milliwatts which when dissipated by the unit will raise its temperature one degree Centigrade above that of its surroundings. Since the temperature rise of a thermistor due to dissipated power depends on the rate at which heat is transferred away from the unit, the dissipation constant depends on the method of mounting the unit as well as the medium or environment in which it is located.

The dissipation constants of a typical 2 in. long glass probe, when supported by its leads in still air, in still oil, or in still water are approximately 1, 3.5, and 5 milliwatts per degree Centigrade respectively.

Time Constant

The thermal time constant, $\tau$, is the time required for a thermistor to change 63 per cent of the difference between its initial temperature value and that of its surroundings when no electrical power is being dissipated in it. With a bead element mounted in a glass envelope or bulb, a disc mounted on a plate, or one or more washer element bolted in a pile-up, the thermal time constant applies to the complete mounted unit rather than the thermistor element alone. It is also assumed that the thermistor element of such a unit is in thermal equilibrium with the remaining components of the unit (i.e., the thermistor element is not in a self-heated condition prior to the introduction of the change in temperature).

1. Dissipation and time constants are based on units being suspended by their leads in still air.
2. Ratio R. @ 0°C/R. @ 50°C
3. Time to reach 63% of applied voltage (seconds) for voltage of 48 v (for this Co.)

ELECTRONIC DESIGN • April 30, 1958
The Advance type SV Sensitive Relay (shown at right) is 1½" high x 2½" long x 2¾" wide. Also available is the type SO Miniature Sensitive Type, 1½" high x 1¾" long x 1½" wide.

SPECIFICATIONS

Coil resistance: From .005 Ohms at .005 volts DC to 40,000 Ohms at 14.0 volts DC.
Nominal power required: Factory adjusted at .005 watts.
Contact rating: 1 amp resistive, .5 amps inductive at 115 volts AC or 28.5 volts DC.
Contact arrangement: SPDT only.

Advance type SV relays are ultra-sensitive, yet durable—dust-tight, yet fully adjustable. Contacts and all working parts are protected by a transparent molded plastic cover.

Sensitivity can be adjusted from the 5-milliwatt factory setting by turning the vernier screws. Use the type SV in any DC circuit where power consumption is limited to a few thousandths of a watt.

Available from leading distributors

WRITE FOR COMPLETE DETAILS

Data sheets on the SV Sensitive Relay and the SO Miniature Sensitive Relay will be sent promptly.

Come to AEROVOX for the widest selection of case styles and constructions in paper, metallized-paper, mica, ceramic, electrolytic, tantalum, and film types in a complete range of miniature and microminiature sizes for every requirement. AEROVOX has the miniature capacitor for your application from low-voltage, long-life components for transistorized assemblies to microminiature units for those critical application requirements in guided missiles and airborne electronic equipment.

Send today for complete technical literature on this extensive line of miniature capacitors to...

BREW’S Complete Facilities offer Reliable Product Performance & Economy with Quality Controlled Production!

- Competent and Experienced Engineering Personnel plus the Latest Testing Equipment guarantee designs to your specifications.
- Modern Assembly Line of Thoroughly Trained Production Personnel assures quality on short or long runs.
- Brew’s Quality Control Program insists on “Component Reliability” as a function of “Systems Reliability” from development to manufacture.
- Special Prototype Department works in conjunction with Brew’s design engineers. Engineering reports accompany prototypes.

Founded in 1946 for design, development and manufacture of delay lines.
Brew offers you the “one source” for Distributed Constant, Lumped Constant, and Ultrasonic Delay Lines. You and your product will benefit from Brew’s modern and complete production facilities, pioneer experience, and complete cooperation from our personnel.

Richard D. Brew and Company, Inc.
Concord, New Hampshire

circle 18 on reader-service card
Long life is achieved by minimizing wear. Wear results from pressures or forces between contact assembly and winding. Total force consists of a dynamic force due to vibration, acceleration and shock; an inertial force acting on the contact assembly; and a static force resulting from contact pressure. For proper operation, contact force must exceed the vector sum of the dynamic forces.

The Kintronic contact assembly is dynamically balanced about a pivot and therefore vibration, acceleration and shock forces cancel out. Inertial force on the contact assembly is minimized by making its mass and size small as possible. Reduction of these dynamic forces enable use of very low contact pressure.

Operational Results: total wear producing force is extremely small. 5,000,000 cycle life is achieved at maximum speeds of 3,425 r.p.m., under 2,000 cycle 30g vibration!

1. Ratio R. @ 0°C/R. @ 50°C

ELECTRONIC DESIGN • April 30, 1958
Since the time required for the thermistor to change its temperature by a specified amount depends on the rate of heat transfer between the thermistor and its surroundings, the thermal time constant depends upon the method of mounting the unit as well as the medium of environment in which it is located. For example, the thermal time constants of a typical 0.4 in. diameter disc, when supported by its leads in still air, in moving air (1000 ft/min), still oil, or moving oil (200 ft/min), are approximately 100, 30, 20, and 5 seconds respectively.

The thermal time constants for a typical 2 in. long glass probe thermistor, when supported by its leads in still air, in still oil, or in still water are approximately 25, 2, and 1 second respectively.

The thermal time constants of a thermistor with leads is usually specified for the unit supported by its leads in still air. For a thermistor which does not have leads, the thermal time constant is specified for the unit mounted in intimate contact with a good thermal sink.

**Temperature Coefficient**

The temperature coefficient of resistance, \( \alpha \), is the ratio of the rate of change of resistance with temperature to the resistance of the thermistor at a specified temperature. It is commonly specified in per cent per degree, or ohms/ohm/degree and may be expressed mathematically as:

\[
\alpha (T) = \frac{1}{R_a (T)} \left[ \frac{d R_a (T)}{d T} \right]
\]

Since the resistance versus temperature characteristic of a thermistor is non-linear, alpha varies with temperature. In general, alpha increases as the temperature decreases and vice versa.
1958 definitely promises to exceed the record-setting volume of our Electronics and Avionics Division last year. And we are not overly optimistic at all in our plans to double these figures during the next few years.

Emerson Electric, a leading medium-size manufacturer of missiles and electronic equipment, has a firmly outlined, long-range expansion program. Our plans require broadening our organizational structure immediately. This has opened unusual career opportunities with complex challenges.

We emphasize research, design and development, and maintain a strong balance in production work. Current projects include the B-58 fire control system, mortar locators, radar components and assemblies, servomechanisms, missiles and rockets, ground support equipment, microwave antennas, F-101 Voodoo subsystems, plus many other classified electronic devices for the supersonic era.

These positions require an E.E. degree plus 4-6 years’ experience in electronics. Experience must include electronic design work in any of the following: servomechanisms, radar systems, analog or digital computers, fire control systems or ground support equipment. Missile guidance and/or infra-red experience will be helpful but is not essential.

Emerson Electric is a well-established dynamic organization with 900 engineers and 5000 employees. Salaries and benefits, including advanced education, are top level. Our suburban location is ideal in every way. All moving expenses are fully paid.

Be sure to send your complete resume NOW, including business experience, education and salary requirements, to A. L. Depke.
Now Penta Laboratories brings to the 500- to 1000-watt output range the advantages of the exclusive vane-type suppressor grid introduced in 1956 with the 1000-watt PL-172. This new 400-watt PL-175 provides 25 to 30% higher output in Class AB1 linear amplifiers than tetrodes with similar ratings— with minimum distortion. A versatile tube, the PL-175 also has outstanding advantages as a Class C r-f power amplifier or high power audio amplifier for modulator service.

Microwave Applications of Thermistors

Leonard I. Kent
Chief Microwave Engineer
The Narda Microwave Corp.
Mineola, N.Y.

A thermal sensitive resistor, the thermistor, is finding wide application in measuring microwave power. Among the topics of importance are thermistor characteristics, thermistor mounts, dc characteristics, broadband mounts, and coaxial mounts. Part II will discuss waveguide thermistor mounts, and measuring techniques.

Part I

There are many devices which are sensitive, with varying degree, to thermal or temperature changes. The thermistor, a thermal sensitive resistor with a negative temperature coefficient of resistance, is one of the more sensitive devices. When a thermistor is subjected to a temperature change, as occurs when it is exposed to electromagnetic energy, it undergoes a very large change in resistance. If the thermistor is small compared to a wavelength, and its resistivity sufficiently great that high-frequency currents are forced to flow throughout the volume of the element, rather than on the surface; the temperature gradients within the volume of the element, and the exchange of heat with the surrounding area, will be almost identical for direct current, audio and microwave frequencies. Since this implies that equal quantities of dc, ac, or rf power absorbed by the thermistor heat it to the same temperature and effect the same resistance change, this principle can be used to measure any of these powers by substitution methods. Of particular interest here is the measurement of rf or microwave power.

Primary equipment needed for the measurement of microwave power are an efficient thermistor mount matched to the transmission line in which it will be used, and a Wheatstone bridge circuit, preferably one which is self-balancing. When a power substitution method is used, the
bridge should be capable of biasing the thermistor to at least the amount of power to be measured, and the thermistor must be capable of withstanding that amount of power. For the measurement of power greater than the element can handle, additional equipment can be used.

**Characteristics of Thermistors**

Thermistors used for microwave power measurements are ceramic semiconductor beads which consist of various mixtures of the oxides of manganese, nickel, cobalt, copper, uranium, iron, zinc, titanium, and magnesium. The materials are mixed in proper proportion to obtain the required specific resistance and temperature coefficient of resistance. To form the bead, two taut platinum alloy wires, 0.001 inches in diameter, are stretched parallel to each other with an accurately controlled spacing between them. The thermistor material in paste form is placed across the gap. Surface tension molds the paste into an approximate sphere with a diameter of 0.015 inches. The sphere is air-dried and sintered under accurately controlled atmospheric and temperature conditions. The leads become embedded tightly in the material, making good electrical contact to it. The finished bead is a hard ceramic material which is enclosed in a thin glass coating protecting it from further oxidation at high temperatures. This coating also greatly aids in the ruggedness and electrical stability of the bead. Diagonally opposite lead wires are cut and the bead cross-section is then as shown in Fig. 1.

**Preliminary Mounting of the Thermistors**

The bare thermistor element can be placed in a mount to which its impedance is matched and then used for microwave power measurements. Although this would serve the purpose, it is not the easiest assembly task to achieve. The extremely small size of the element makes it necessary for a skilled technician to do the assembling. In addition, when the bead has to be replaced, the user must acquire another bead and endure the hardship of soldering the new bead in the mount, or else send the unit back to the manufacturer for the replacement of the thermistor. The logical approach, then, is to put the thermistor element into a form which is conveniently replaceable.

Figs. 2(a), 2(b), & Fig. 5 show appropriate forms in which thermistors can be placed so that they can be easily handled and readily replaced. The element shown in Fig. 5 is a mica disc upon which two thermistors are mounted. This unit is specifically designed for use in a mount which can be used to measure power in a coaxial transmission line. Fig. 2(a) shows a cartridge which is similar in shape to the body of a 1N21 and 1N23 crystal. One or two thermistor beads can be mounted in this unit, dependent upon its application. This element is primarily used in mounts which measure power in waveguide systems. Fig. 2(b) shows a miniature version of the Fig. 2(a) unit. This is used in waveguide mounts for the higher frequency ranges. Further details of the construction of these elements are discussed in subsequent paragraphs.

**DC Characteristics**

Typical curves of the dc characteristics of the thermistor units are shown in Fig. 3. This curve is typical for the disc element in an appropriate coaxial mount and the cartridge units in a representative waveguide mount. The data variation among elements or mounts stated in the curves are due primarily to two factors. One is the difference in characteristics among thermistor beads and the other is the difference in the immediate surroundings within the mounts in which the elements are placed. The length of the 0.001-inch diameter leads and the effect of conductive and convective heat losses affect the dc characteristics appreciably. By keeping the leads uniform in length for the particular types of elements, some of the variational effects are reduced. Each mount, though, will still present at least a slightly different environment to the element, so that the dc characteristic can not be absolutely uniform among mounts designed for various frequency ranges. The variations of the dc characteristics are particularly important if a self-balancing bridge circuit is not used for the power measurements.

Experience has shown that these thermistor elements should operate within the range of 100 to 300 ohms in order to obtain the optimum conditions of good bridge sensitivity, ease of impedance-matching the thermistor to the mount, and protection from overload or burnout of the beads. Therefore, when a single-bead thermistor is used, it is usually biased to 200 ohms, and two beads in series are biased to 100 ohms each. The latter, of course, requires a larger bias current to obtain necessary resistance. This is advantageous in the substitution method of measuring microwave power, since a greater amount of rf power can now be substituted for the power that biases
the element than if a single bead were used. Fig. 4 shows the bias current as a function of temperature necessary to obtain the overall 200 ohms for the beads connected in series in waveguide and coaxial mounts.

**Broadband Thermistor Mounts**

One of the most important items required for microwave power measurements is a mount whose impedance is matched to the thermistor it houses, and is also matched to the transmission line in which it will be used. To be completely versatile, the thermistor mount should be well-matched over as large a frequency range as possible with no tuning necessary. It should also be able to maintain a good match with any of the same type of elements that may readily be placed in it. Not only would this mount need no adjustments by the user, but no factory adjustments would be required by the manufacturer.

By matching the thermistor mount to the transmission line over a broad frequency range, the error due to the loss of power by reflection is minimized. Another factor requiring attention, however, is inefficiencies in the mount. There must be no microwave power leaking from or into the mount, and no sources of power dissipation other than the thermistor beads must exist. Lossy tuning devices and defective electrical contacts must be completely avoided. With these points in mind, excellent coaxial and waveguide thermistor mounts can be designed.

In Fig. 5, the internal construction of a broadband coaxial thermistor mount is shown. Also shown is the construction of a mica disc thermistor element. The element contains sprayed silver electrodes upon which two thermistor beads are mounted. The principles by which the mount and element operate can be described with the aid of the equivalent circuit of Fig. 6. The two beads are placed in series for the external bias circuit and in shunt across a 50-ohm coaxial line. When the beads are biased to present a resistance of 200 ohms to the external bridge circuit, each bead is biased to 100 ohms. To the rf line, the two beads are in parallel, thereby presenting a thermistor rf resistance of 50 ohms. Bias connections are provided by one end of a thermistor bead being isolated from the outer coaxial conductor by means of an rf by-pass capacitor, and the end of the other bead connected to the outer conductor, which is ground for the external circuit. An rf blocking capacitor isolates the center point between the two beads from the center conductor of the rf coaxial line. Both capacitors are in the form of silvered circular electrodes on a thin mica insulator. The underneath of the center conductor of the mount in Fig. 5 provides a series inductance to match any reactance of the thermistor beads, as well as the fringing capacity caused by the sudden termination of the coaxial center conductor. The center conductor bead support shown in the figure has been designed to give negligible reflections over the operating range.

![Fig. 5. Construction of a broadband coaxial thermistor mount and a mica disc thermistor element.](image)

![Fig. 6. Equivalent dc circuit of broadband coaxial thermistor mount.](image)

![Fig. 7. Photograph of coaxial mount opened to replace the element. It can be used with disc bolometer elements.](image)

![Fig. 8. Coaxial thermistor mount using two replaceable cartridge thermistor elements. Blocking capacitors are built into the mount.](image)
The coaxial thermistor mount is designed to operate over the frequency range from 500 to 10,000 mc. The vswr of the mount over this range is always less than 1.50. This corresponds to a power reflection loss less than 0.2 db. Operation below the lowest frequency is limited by the blocking capacitor, while at the highest frequency, the coaxial connector limits the operation. The disc thermistor element is capable of measuring power levels from 0.01 to 10 mw. The design of this element embodies the considerations given it for ease of handling and replacement of a damaged element. Uniformity is maintained very closely in its manufacture so that the replacement of a thermistor element does not adversely affect the broadband characteristics of the mount. A photograph of the coaxial mount is shown in Fig. 7, and how it appears when opened to replace an element. As an incidental feature, besides being used as a thermistor mount, this unit can be used with various disc bolometer elements which are available. The principles of operation for bolometers in this mount are similar to those described for the thermistors. This mount offers a broadband match (vswr < 1.50) to four types of bolometers that require bias currents of 4.5, 8.75, or 35 ma. The arrangement of the locating pin in the descriptive nameplate makes it possible to change elements rapidly, and to determine at a glance which type of element is in the mount and its bias requirements.

Another type of coaxial thermistor mount (see Fig. 8) can be briefly mentioned here. This fixed tuned mount makes use of two replaceable cartridge thermistor elements as shown in Fig. 2(b), each containing a single thermistor bead. As with the disc's thermistor beads for the 561 coaxial mount, the two cartridges are placed in series for dc, and in parallel for rf. The parallel combination is again similarly made to present a 50-ohm impedance to the input coaxial line. Necessary blocking capacitors are built into the mount. This coaxial mount can be used over the frequency range from 20 to 1500 mc with a vswr less than 1.20. Similar to the 561 thermistor mount, this mount can also give equal performance with the appropriate cartridge type 100-ohm bolometers which are available. (This is the first of two articles on Microwave Applications of Thermistors.)

Two seconds to "FIRE"...the time when your instrumentation cables must work

Are you responsible for any of the equipment involved in scenes of this kind? Any of the instrumentation or telemetering devices?

If so, you well know how little can be left to chance when a $100,000-plus pre-dawn "shot" is scheduled.

Even minor cable trouble at a time like this can be crucial and costly, especially if it happens on the equipment involved for which you are responsible.

That's why it's important for you to insist on electronic cables with maximum built-in reliability.

Quiz yourself on cable

Here's how to get this kind of reliability. Ask yourself these questions about the cable that's to go into your own equipment:

1. Who is the cable supplier? Has he:
   a. Thorough knowledge of electronic wiring problems?
   b. Engineering and research skill in developing special cable?
   c. Complete facilities for producing custom-built or specification cable?
2. Are his cable conductors full-size, uniformly annealed and precisely stranded?
3. Are his insulations and coverings uniformly applied compounds that have proved workable, dependable?
4. Can he supply those newly developed materials that might be needed?

You'll find all of these qualifications met in full measure by Rome Cable

Millions of feet of Rome wire and cable have already been installed in electronic gear for military and commercial uses. More is ordered every day.

When you require cable that must not fail—or which must meet unusual specifications—we can very probably help you. Simply contact your nearest Rome Cable representative—or write to Department 422, Rome Cable Corporation, Rome, N. Y.
4 Ounce Contact Force Gives Relay Reliability

Contact force of 4 ounces per contact on 50 "G" models and 2 ounces per contact on 30 "G" models of "Diamond H" Series R and Series S miniature, hermetically sealed, aircraft type relays is one of the most important factors in their proven high reliability.

Though absolute reliability of any similar device is impossible to guarantee—a bitter fact of life recognized by all electronic engineers—close approach to this goal by the relays manufactured by the Hart Manufacturing Company is the basic reason they are found today on many of this country’s headline-making missiles.

In addition to contact force far beyond that found on other relays, “Diamond H” relays have greater contact cleanliness. Self-contamination is virtually eliminated by a completely inorganic switch mechanism, as well as use of coil materials which will not dust, flake or out-gas.

Finally, the high degree of reliability that is designed into these relays is maintained in their manufacture by high quality workmanship and a stringent inspection policy at every stage.

In addition to missiles, and their ground control systems, Series R and S relays are designed for use in jet engine controls, computers, fire control, radar and similar critical applications.

4PDT units, they offer an extremely broad range of performance characteristics, including temperature ranges from —65° C. to 125° and 200° C.; ratings to 10 A., 120 V., A. C., and 26½ V., D. C., with special ratings to 400 ma. at 350 V., D. C., or down to millivolts and milliamperes. Dry and wet circuits may be safely intermixed.

For more information, write today for Bulletins R250 and S260. For quick facts about "Diamond H" switches, thermostats and other devices, ask also for a copy of the "Diamond H" Check List of Reliable Controls.

THE HART MANUFACTURING COMPANY

CIRCLE 23 ON READER-SERVICE CARD
LOW-TEMPERATURE thermistors are very useful to measure temperatures of missile fuel components. New low-temperature types have been designed which work in liquid oxygen, nitrogen, and hydrogen. Thermistors are desirable replacements for helium gas and platinum resistance thermometers because they are less expensive, much less breakable, and much more sensitive. The gas thermometer has additional shortcomings in that it does not produce electrical signals directly and cannot be easily miniaturized.

Fig. 1. Temperature coefficient in % per degree C as a function of B for —183.3, —195.6, and —252.8 C. B is calculated from the resistance ratio: R — 183.3 C/ R + 20 C.
The usual commercial thermists with negative temperature coefficients between 2 and 8 per cent per degree at room temperature cannot be used for very low temperatures. In liquid oxygen (−183.3°C) the resistance would be increased to values above 10 megohms, which are inconvenient for electronic circuitry. The new types of thermists developed for applications at such low temperatures are described in this article. Data on wattage rating, time constant, and reliability estimates are given.

**Resistance**

Various resistance materials have been developed to cover the temperature range between liquid oxygen and liquid hydrogen with resistance values which are practical for normal circuitry. "Large" temperature coefficient materials can only be used down to −220°C, while "small" temperature coefficient materials were developed for applications down to −255°C. The classification "large" and "small" temperature coefficient is arbitrary and refers to the behavior of the materials in liquid oxygen. At room temperature both materials have a very low temperature coefficient. On the other hand, in liquid hydrogen, the "low" temperature coefficient would increase to 50 to 75 per cent per degree. See Table 1.

Further variations, though only to a lesser degree, can be made by changing the geometrical dimensions of these units. By producing thermistor units either in disk or rod type, a resistance range of more than one decade can be covered by the same material. Simultaneously, the self-heating and wattage rating of these units, which are determined by the values of their mass and surface, can be varied within certain limits. The same holds true for their response to temperature changes (time constant).

The gap between "large" and "small" temperature coefficient thermists is expected to be closed soon by new thermistor types.

The exponential increase of the resistivity of thermists with decreasing temperature is expressed in first approximation by the formula:

\[ \log \rho_1 \rho_2 = B (T_2 - T_1) \]

in which \(\rho_1\) and \(\rho_2\) represent resistivities at the respective absolute temperatures \(T_1\) and \(T_2\) in degree Kelvin (degree K = degree C + 273.15).

For a given temperature interval \((T_2 - T_1)\) the constant \(B\) is a linear function of the Briggs logarithm of the resistivity ratio between \(T_1\) and \(T_2\). On the other hand, \(B\), Fig. 1, is truly constant only for smaller temperature intervals. It has its own temperature dependence, which however is small and tends to decrease the \(B\) value itself and correspondingly the resistivity ratio, thus extending the application range of these thermists to lower temperatures.

Values below 2000 are of practical interest because of high resistance values involved.

Depending on B or the ratio group: See Fig. 1.

Note that the range of possible resistance values at temperatures below −183.3°C becomes larger.

This effect is most welcome for ultra low temperatures in the order of −253°C (20 deg K) where it helps to shift the limit of application 3 to 4 degrees lower. For a truly constant \(B\) the resistivity would be a linear function of \(1/T\), the reciprocal absolute temperature in degree Kelvin.

In Fig. 2 the resistivity versus temperature characteristics of various thermistor types are compared with that of carbon resistors which during the past few years have been recommended for temperature measurements below 4 deg K. From the illustration, four facts are evident:

- The resistivity of commercial thermists is sky high in the liquid oxygen range.

</table>

This type listed above are not available in all materials and resistance values. Disk types are preferred for "small" temperature coefficient materials, but by no means restricted to them. On the other hand, standard rods are normally made of "large" temperature coefficient materials, as are also midget rods. The latter have played a minor role in electronic design till now.
factor is the heat conduction of the lead wires. Economical considerations impose some restrictions on the variety of types with regard to the physical dimensions and the contact leads. Table 2 describes these features for the principal types.

**Wattage rating.** The wattage which can be applied to these thermistors without changing their value beyond certain limits by self-heating is influenced not only by their geometrical dimensions and their mass, but also by their temperature coefficient and the heat dissipation into the surrounding medium. Heat capacity, viscosity, and, for liquid gases, pressure and heat of evaporation, will determine the dissipation. Table 3 refers to thermistors immersed in liquid oxygen at its boiling temperature. The per cent resistance decrease for various thermistor wattage ratings is shown.

</tbody>
</table>

The relatively high resistance change for standard rods compared to disks shown in Table 3 evidently results from the large temperature coefficient material normally used for this type. The temperature increase for 100 mw corresponds to 0.5, 0.25, and 0.35 C, respectively.

**Time constant.** The time which is necessary to reach 63 per cent of the final value when submerging a thermistor of room temperature into liquid oxygen is listed for several types in Table 4.

Under equal cooling conditions the time constant should be in first approximation proportional to the heat capacity or the mass respectively of the unit. However, the data of Table 4, by no means, reflect the decrease in mass from standard to midget size.

The formation of gas bubbles, though only transient, during the dipping of the units into the boiling oxygen apparently distorts the cooling conditions and obscures the true time con-

---

**LA-260 Oscilloscope**

The first CRO designed to military requirements with plug-in single or dual trace vertical preamplifiers. New technique permits all d-c supply voltage regulation to better than 0.1% ... including d-c filament voltage. Flat 5" CRT increases viewing area, screen visibility from greater distances. Improved electron optics assure brighter high-speed pulse traces.

**LA-80 Electronic Counter**

High reliability and wide frequency range are featured in this superior designed counter. Eight-place, in-line read outs afford clear, sharp digits, visible at any angle. Other features include MIL spec design, temperature insensitivity, wide time interval range and simplified circuitry.

**LA-70 Frequency Meter**

Generates and measures frequencies from 10 KC to 3000 MC with 1 x 10−4 accuracy ... particularly suitable for VHF receiver measurements in mobile service ... weighs only 42 pounds. Oscillator is stabilized by use of thermostatically controlled 1 MC precision quartz crystal. Stability over six months — 1 part 10−6.

**LA-90 10−9 Frequency Standard**

Based on new approach to precise crystal oven regulation to provide (1) long term temperate life (2) excellent stability over wide ambient temperatures (3) elimination of permanent temperature shifts found in thermostat or thermistor devices, and (4) use of JAN tubes and magnetic beam switching tubes for reliability.

Morganville, New Jersey
stent. A similar effect is observed when water is dropped onto a red hot steel plate. The water does not evaporate explosively, but a few water drops "swim" a few seconds on a heat insulating cushion of water vapor (Leidenfrost phenomenon). The true time constant of these units measured without formation of gas bubbles, e.g., non-evaporating media, will be smaller. In order to provide some data for the calculation of temperature adaptation processes, the approximate specific heat in cal/gram of these materials is given: $20^\circ C = 0.15; -200^\circ C = 0.08; -230^\circ C = 0.04$.

For temperatures below $-230^\circ C$ the specific heat will drop further at an increased rate, thus decreasing the time constant. This effect is most welcome insofar as it opens the possibility to apply larger and more rugged thermistors at very low temperatures (<30 deg K). In other words, larger units behave as if they had a smaller mass.

**Reliability.** Life tests were carried out in two different ways.

**Long term life tests:** Consecutive cooling cycles from room temperature to $-183.3^\circ C$ and back were made with storage periods at ambient temperature between the cooling cycles.

**Short term life tests:** Repetitive cycles were made either between room temperature and liquid oxygen or between liquid oxygen and liquid nitrogen temperature.

Since resistance changes alone are not conclusive enough because of the different temperature coefficients for various types and ratio groups, it is more informative to express reliability data as possible temperature errors produced by resistance deviations with time.

Possible temperature error:

- In short term life tests $\pm 0.2^\circ C$.

It is obvious that the electrical stability of these thermistors is in some degree dependent upon the cooling rate. The life test cycles were always made by direct quenching in liquid gases and reheating in air of ambient temperature. The thermal shock during quenching in the liquid is exceptionally rough. It can be compared to the quenching of other electronic components from 200°C in air into ice water, a test which normally is not applied.

Since certain applications call for a better long term stability, higher quality grades can be obtained by proper classification and treatment. However, as usual, quality requirements and economy will have to be matched by the designer.

**Protective coatings.** The high insulation resistance of liquid gases and their chemical indifference makes it superfluous to apply insulating or protective coatings. Furthermore, many of the conventional coating materials such as plastic films become very brittle at low temperatures and do not withstand consecutive quenchings. Nevertheless, special coatings have been investigated which hold promise of being satisfactory in this temperature range.

**Acknowledgement:** The author wishes to thank Mr. G. W. Vollmer for his assistance and Keystone Carbon Co. for granting permission to publish this information.

**References**

First basic facts on low temperature thermistors were published in:

The increasing use of thermistors has made adequate military specifications a necessity. As yet no standardization efforts have been made by the Armed Services or by industry. This general specification for procurement of thermistors was prepared by R.C.A. for military airborne equipment. It has enabled the purchase of reliable thermistors for the past few years.

The most widely known characteristic of thermistors is its variation of dc resistance value with temperature. This property is not quite the same thing as "temperature coefficient of resistance" for resistors. The resistance-temperature characteristic can be closely described by:

\[ R(T) = R_0 e^{\beta \frac{(1/T_0 - 1/T)}{T}} \]  

where: \( T_0 \) and \( T \) are the references and test temperatures, respectively, in degrees Kelvin, \( \beta \)—material constant

Since thermistors exhibit relatively large changes in dc resistance with small temperature swings, the specification should carefully indicate the test procedure for evaluation.

Resistance-Temperature Characteristic

Thermistors should be mounted at least one inch apart on suitable mounting strips. Three temperature baths should be available to provide controlled temperature environment over an extended period of time. The temperatures should be controlled within ±0.05 degrees C and should consist of one of the group options listed below:

<table>
<thead>
<tr>
<th>Option I</th>
<th>Option II</th>
<th>Option III</th>
</tr>
</thead>
<tbody>
<tr>
<td>0°C</td>
<td>-21.5°C</td>
<td>37.8°C</td>

<td>25.0°C</td>
<td>25.0°C</td>
</tr>
<tr>
<td>50°C</td>
<td>37.8°C</td>
<td>104.4°C</td>
</tr>
</tbody>
</table>

The thermistors should have their dc resistance value measured at the listed temperatures, in the order shown, with a Wheatstone bridge which is accurate to ±0.05 per cent. The resistance values measured at the low and high temperatures shown above (0°C and 50°C, -21.5°C, and 37.8°C, or 37.8°C and 104.4°C, respectively) should be used to calculate the material constant (beta or "b") of each sample for comparison with subsequent measurements. The 25°C resistance measurements should be only to initially check
The commonly-specified 25°C resistance tolerance. The following formulas should be used in the material constant calculations with Options I, II, and III, respectively:

\[
\text{Material Constant } = \beta = 4056 \log \frac{R_0}{R_60^\circ C} \quad \frac{R_{21^\circ C}}{R_60^\circ C} \quad \text{or} \quad 4056 \log \frac{R_{37.5^\circ C}}{R_{104^\circ C}}
\]

**Voltage-Current Characteristic**

This characteristic is extremely important in many thermistor applications where self-heating is an integral part of the circuit design. Thus, the test procedure should be carefully stated so that the desired performance is indicated.

The thermistors should be mounted with the leads soldered 1-1/2 ±1/8 inch (effective length)

CIRCLE 27 ON READER-SERVICE CARD
Why synchronize two drive systems, handle two chart rolls, or for that matter, maintain two separate instruments? The DUAL "recti/riter" gives you two independent galvanometers, inking systems, and "recti/rite" linkages—with a single chart drive—enables you to record two variables simultaneously and visually correlate events to an accurate common time base. Record such variables as voltage and current, wind direction and velocity, temperature and pressure, torque and speed, input and output, and many others.

And have the easiest of all recordings to read—true rectilinear side-by-side traces that you read at a glance with a simple ruler... no difficult interpretations so highly subject to reading errors as with old-fashioned curvilinear recordings.

Add these to the other outstanding features of the "recti/riter"—galvanometer accuracy, easy frontal access for all routine operations, fingertip control of 10 chart speeds, dependable closed inking system, AC, DC, spring, or external drives... and you have the most work-saving recorder available.

Remember, too, that only the "recti/riter" and matching accessories provide these wide ranges for recording electrical parameters:

- 10 millivolts to 1000 volts
- 500 microamperes to 1000 amperes

Monitor standard frequencies—40, 60, 400 cps

When you write for specific information on the DUAL "recti/riter", Bulletin R-502, ask TI to include facts on the SINGLE "recti/riter", Line Voltage Monitor, and Model 301 All-Transistor DC Amplifier. You will be interested in the complete versatile line.

Specifying Military Thermistors continued

from the body and in still air at 25°C. The test circuit should be that shown in Figure 1. The series-limiting resistors (R₁ and R₂) shall be such that initially the circuit current will not cause self-heating in the thermistor sample. The circuit current should then be increased in the sequence shown in Table I and the corresponding voltage measurements should be made. A stabilization period, not to exceed 15 minutes, should be allowed at each sequence prior to recording values.

The nominal 25°C current rating should be calculated as:

$$I_{(\text{nom. } 25^\circ C \text{ rating})} = \left(\frac{P_{(\text{nom. } 25^\circ C \text{ rating})}}{R_{(\text{nom. } 150^\circ C \text{ value})}}\right)^{\frac{1}{3}}$$

Qualification Tests

As a condition for granting engineering approval a group of specimens should be submitted to a qualification test procedure designed to determine whether they meet minimum acceptable quality levels. The determination of those limits should be the result of an initial study of thermistor performances when subjected to the usual military specification environmental tests. A study of this nature has been completed by the Radio Corporation of America, Camden, N.J. The qualification test procedure, as used by RCA, Defense Electronic Products, is in Table II.

Adequate precautions should be taken during tests to prevent moisture condensation on specimens, except during the Moisture Resistance and Temperature Cycling Tests.

Failure of a single thermistor in one or more tests of a test group should be charged as a single failure. One failure should be permitted in each test group but no more than two should be permitted for all test groups combined.

When thermistors as a group fail a specified average percent-change requirement, only one failure should be charged; however, a failure should be charged for each thermistor of the group which exceeds the maximum percent-change requirement, and these thermistors should not be considered in computing that average. It is intended to permit one average percent-change failure to be charged for the material constant requirement and an additional failure for the resistance change requirement.
The Resistance-Temperature and Voltage-Current Characteristic Tests have already been described.

**Low Temperature Exposure**

After a 24 hour exposure at \(-80^\circ\text{F}\) \((\pm 2^\circ\text{F},\) \(0^\circ\text{F})\) the resistance-temperature characteristic should again be performed.

The average change in the material constant for a group of specimens should not exceed \(\pm 0.5\) per cent, nor should an individual specimen have a material constant change greater than \(\pm 1.0\) per cent. The average change in the resistance value for a group of specimens at \(0^\circ\text{C}, -21.5^\circ\text{C}\) or \(37.8^\circ\text{C}\) should not exceed \(\pm 3.0\) per cent, nor should any individual specimen have a resistance change (from initial \(37.8^\circ\text{C}, 0^\circ\text{C}\) or \(-21.5^\circ\text{C}\) value) greater than \(\pm 5.0\) per cent.

**Temperature Cycling**

Specimens should be subjected to the Method 102, MIL-STD-202, condition A test. No subsequent measurements should be required. Mounting should be as specified in the Resistance-Temperature Characteristic Test.

The specimens should be inspected for evidence of mechanical damage and discoloration of the color coding which renders it unrecognizable from the specimen background color.

**Moisture Resistance**

Specimens should be subjected to the Method 106, MIL-STD-202 test. Mounting should be as specified in the Resistance-Temperature Characteristic Test. No load or polarizing potential should be applied to the specimens during the test. Final measurements should be made after the 24 hour room ambient conditioning following the tenth cycle. The Resistance-Temperature Characteristic Test should be performed. Per cent change of resistance value at \(0^\circ\text{C}, 37.8^\circ\text{C},\) or \(-21.5^\circ\text{C}\) and material constant \((b)\) should be calculated.

The average change in the material constant for a group of specimens should not exceed \(\pm 5.0\) per cent, nor should an individual specimen have a material constant change greater than \(\pm 10\) per cent. The average change in the resistance value for a group of specimens at \(0^\circ\text{C}, -21.5^\circ\text{C}\) or \(37.8^\circ\text{C}\) should not exceed \(\pm 10\) per cent, nor should an individual specimen have a resistance change (from initial \(37.8^\circ\text{C}, 0^\circ\text{C}\) or \(-21.5^\circ\text{C}\) value) greater than \(\pm 12\) per cent. Evidence of galvanic action within a specimen should be considered as cause for rejection as a defective specimen.

**Terminal Strength**

*(applicable to rod thermistors only)*

Thermistors should be held by a terminal and tensile force should be gradually applied to the
What do you want in a plastic laminate?

RICHARDSON INSUROK® fills many needs

The table of electrical properties shows but a few of Richardson's phenolic laminates which are used extensively for a wide variety of electrical, electronic, and mechanical applications.

These laminates are furnished in standard NEMA grades and many special grades which were developed for radio, television, and other electronic communications components where stability under heat and humidity is essential. In thin sheets INSUROK punches clean and sharp for fabricating. The heavier sections have good machining and mechanical properties.

The quality of INSUROK is rigidly controlled through each step of processing and is your guarantee that its performance will satisfy your requirements.

More detailed information on electrical properties is available for the asking. Write for the Laminate Catalog. For copper-clads ask for Catalog No. 20.

Specifying Military Thermistors continued

other terminal in the direction of the longitudinal axis until the applied load reaches 3 pounds. Each wire lead should be bent through 90° at a point 0.25 inch from the body of the thermistor, and rotated through 360° in alternating directions for five cycles, at the rate of approximately 5 seconds for each complete cycle.

Terminals should withstand a direct pull of 3 pounds and the five twist cycles without evidence of mechanical failure.

Effects of Soldering

Thermistor terminals should be immersed individually for 3 ± 1/2 seconds in a pot of molten solder at a temperature of 350 ± 10°C to a point one-eighth to three-sixteenths inch from the thermistor body.

There should be no evidence of mechanical damage, loosening of terminals or discoloration of color coding beyond ability to distinguish from the specimen background body color.

Body Strength (applicable to rod thermistors only)

Specimens should be supported one-eighth inch from each end, and should then be subjected to a transverse load of not less than 4 pounds. The load should be applied at the center of the thermistor through a fulcrum having a radius of not less than 0.25 inch.

There should be no evidence of mechanical damage, breaking, or splitting of the specimen's body.

Load Life

The thermistors should be mounted on terminal strips with terminals spaced two inches apart, so that the effective lead length (including the height of the terminal post) is not greater than 1 inch.

Thermistors should be placed in an oven whose temperature is then brought to 125°C ± 2°C within two hours from room temperature. A current equivalent to 10 per cent of the nominal 25°C current value should be drawn by each thermistor for 1000 (+0, -8) hours. The power...
supplies should then be disconnected and the doors of the oven may be opened so as to allow the oven temperature to return to room conditions in not less than two hours. Final measurements of Resistance-Temperature Characteristic should be made and per cent change of resistance value at 0°C, 37.8°C or -21.5°C and material constant should be calculated.

The average change in the material constant for a group of specimens should not exceed ±1.0 per cent, nor should individual specimen have a material constant change greater than ±3.0 per cent. The average change in resistance value for a group of specimens at 37.8°C, 0°C or -21.5°C should not exceed ±3.0 per cent, nor should any individual specimen have a resistance change (from initial 37.8°C, 0°C or -21.5°C value) greater than ±5.0 per cent.

**Vibration**

With the component mounted rigidly as intended, vibrate according to the following information noting all resonant frequencies:

- Frequency range: 5 to 500 cps. 5 to 500 and back to 5 in 15 minutes.
- Repeat 8 times (2 hours) for modes 1, 2, and 3, below.
- Total excursion or acceleration: ±0.01 in. or ±5g, whichever is maximum.
- Mode (1) Horizontal-parallel to major axis.
- Mode (2) Horizontal-perpendicular to major axis.
- Mode (3) Vertical.
- Resonance running time: 30 minutes at each noted resonant frequency.

If any mounting bracket resonance occurs below or at 55 cps, run for 30 minutes at that frequency with total excursion of 0.60 inch.

There should be no evidence of mechanical damage to the wire leads, breaking or splitting of the specimen’s body.

**Shock**

Subject the part to 50 impact shocks which have an amplitude of 30 times the acceleration of gravity, each shock impulse having a time duration of 11 + 1 millisecond. The shocks should be applied in the following directions:

- Horizontally, parallel to the major axis, five shocks in each direction.
- Horizontally, perpendicular to the major axis, five shocks in each direction.
- Vertically, five shocks in each direction.

There should be no evidence of mechanical damage to the wire leads, breaking or splitting of the specimen’s body.

The procurement drawing covering the above tests and requirements has permitted RCA to buy reliable thermistors during the past few years. It is expected that a future evaluation of the qualification test results will permit reduction of allowable change levels.

Thermistor Bridges

Marsden L. Miller
Chief Engineer
Victory Engineering Corp.
Union, N. J.

Significant advantages can be obtained from the relatively large outputs rendered by thermistor bridges. Temperature sensing circuits become quite involved because of the inherently low outputs from most transducers. A basic sensing circuit with a reasonably high output offers important savings and increased reliability. Three thermistor bridges with relatively large outputs are compared with those of several types of a more familiar device, the thermocouple.

Thermistor Self-Heating

Before proceeding directly to bridges there is one further item that must be thoroughly understood. Since thermistors are basically resistors, they will heat up appreciably if sufficient current is passed through them. The resultant temperature change should be accounted for.

For instance, suppose that it were required to measure the temperature of water flowing through a large pipe at a varying rate. Further, suppose the thermistor, which of course is the sensing element, is heated so that its temperature is three degrees above that of the water when the water is flowing slowly. When the water speeds up it will not draw off more heat from the thermistor than before. If it is assumed the increased flow cools the thermistor so that it is now only two degrees above the water temperature, a one degree temperature change has been introduced in the measurement, and the water, for all practical purposes, has not changed temperature at all.

How is this change eliminated? Simply keep the power dissipation in the thermistor low.

Fundamentals

Thermistors in general have very high negative temperature coefficients, that is, they drop drastically in resistance as the temperature rises and vice versa. This function is depicted graphically in Fig. 1.

Thermistors presently are available in resistance values from a matter of a few ohms to tens of megohms. Since they are very temperature sensitive, a reference point of 25°C (77°F) is usually assumed as the temperature at which they are measured. For instance, a thermistor which is purchased as a one thousand ohm unit has been tested to within its specified tolerance at exactly 25°C. For values of resistance at other temperatures there is a graph or table of values usually covering the range of about -50 to 300°C. For those who may wish to calculate the values, the following approximate formula may be applied:

\[ R_1 = R_2 e^{\frac{1}{T_1 - T_2}} \]

where:
- \( R_1 \) = Thermistor resistance at temperature \( T_1 \)
- \( R_2 \) = Thermistor resistance at temperature \( T_2 \)
- \( e \) = Naperian base \( \approx 2.713 \)
- \( \beta \) = Material Constant (°K)
- \( T_1 \) = Reference temperature (°K) of thermistor
- \( T_2 \) = Another thermistor temperature (°K)
enough so that its temperature rise is less than the desired accuracy of measurement. For, if it is desired to measure a temperature accurately to one degree F, the thermistor temperature rise due to electrical current flow must be kept less than one degree.

Each unit's heating capacity is described as a dissipation constant which states the number of watts or milliwatts required to heat up a particular thermistor one degree Centigrade. If a unit were to have a dissipation constant of say two milliwatts per degree Centigrade, ten milliwatts of power would cause the thermistor to rise approximately five degrees above its surrounding medium. When the thermistor is dissipating a negligible (for the problem in question) amount of power, it is said to be non-self-heated. In contradistinction, if the unit is heated appreciably above its medium, it is said to be self-heated. Incidentally, many applications require this latter condition.

Simple Bridge

Fig. 2 is the simplest bridge configuration possible. All further discussion will be based on use of this rather familiar circuit.

Assuming an equilateral bridge, one in which all legs are initially equal, \( A = B = R = T \). The power source \( V \) may be in any form desired such as a battery, voltage regulator tube or transformer. Note that alternating currents may be applied as easily as direct currents.

If the only element in the bridge to vary is \( T \), and the output load \( L \) is matched to the bridge for maximum power transfer; i.e. \( L = A = B = R \), then the curve in Fig. 3 will describe the output current characteristics where all the aforementioned elements are one ohm and the applied potential is one volt.

If a thermistor is placed in position \( T \), the curve of current output that will now be derived as the thermistor changes resistance with temperature is shown in Fig. 4.

Note the relatively wide range of temperature over which good linearity is obtained. This range runs from about 10°C to 60°C, or 50°F to 140°F, a span of room temperatures any section of...
which will plot out on a meter scale as practically a linearly divided arc.

For a practical case, the problem of temperature measurement over only a one degree Centigrade span will be examined. Suppose that in particular a plate of copper is varying between 25 and 24 C. An approach to this rather difficult problem is to construct a bridge as shown in Fig. 5. From the meter's scale we wish to read off temperature divisions of .01 degrees C. Obviously this can be done only if the thermistor has the sensitivity to deflect the meter at least to full scale.

The thermistor indicated is a Veco washer type 21W1 and is approximately 0.77 in. in diameter by 0.048 in. in thickness. It has a convenient mounting hole with approximately a 0.25 in. diameter by which it may be screwed or bolted directly to the copper plate and is specified as 100 ohms ±10 per cent at 25 C. Data from the Veco catalog indicates also that this unit has a dissipation constant of approximately 800 mw per degree C. If the requirements demand that the thermistor contribute no more than 0.01 degree C error, this means that no more than 8 milliwatts can be dissipated in the unit. Using formula (2), the required bridge voltage (2E) is found to limit the thermistor to 8 milliwatts. The necessary bridge voltage is approximately 1.8 volts as shown in Fig. 5.

Data further reveals that the 21W1 thermistor changes about .44 per cent/°C at 25 C. With this knowledge, an approximation can be made of the output meter current. This shall be done by employing Thevenin's Theorem. With the meter out of the circuit the output bridge voltage is derived from divider relations in Fig. 6. This is now the Thevenin voltage of the circuit when the thermistor changes from 25 C to 24 C or 100 ohms to 104.4 ohms. Since the Thevenin resistance of the circuit is relatively unchanged by this small leg shift, we shall simply approximate it as 101 ohms. Therefore, the complete Thevenin circuit of our bridge is as shown in Fig. 7.

When the meter is connected into the bridge, the calculation of its current is quite simple:

\[ I_m = \frac{V_T}{R_T + L} = \frac{0.0216}{101 + 100} = 107 \mu A \]  

It is seen that the meter can be driven well off scale by the small change in temperature of only one degree.

For the next bridge example, a relatively high resistance thermistor is utilized since the object will be to develop a high voltage output from the bridge. The unit employed will be the Veco type 71A2. It is a bead in a glass rod and has a shape very similar to a standard one watt size carbon resistor with axial leads. The ratings of the 71A2 are:

- Resistance at 25 C = 12 Megohms ±20%
- Dissipation Constant = 5 mw/°C in water
- Maximum Power = 0.1 watt
- Temperature Coefficient = -5.8%/°C @ 25°C
- Maximum Temperature = Approx. 500°C

Let us now construct another equilateral bridge using the 71A2 and check its output for a single degree change with less than 0.01 degree C self-heating. From formula (2) we find

\[ E = \sqrt{PR} = \sqrt{(0.00005 \times 12,000,000)} = 24.5 \text{ volts across thermistor} \]

Therefore the bridge voltage (2E) is 49 volts. If the 71A2 is changed to 24 C its resistance will rise to approximately 12.7 megohms. Using formula (4) we find the output \( (V_o) \) to be:

\[ V_o = \left(\frac{T + B}{2}\right)2E = \left(\frac{12.7}{12.7 + 12.0}\right)49 \]

\[ = 0.686 \text{ volts output} \]  

(4)

Now by simply placing another 71A2 in leg A of the bridge, the output may be more than doubled, thus rendering a total output of over 1.4 volts for only a one degree change! Of course this bridge is unloaded and has a very

---

**Fig. 5.** Practical bridge for temperature measurement over one degree centigrade.

**Fig. 6.** Approximate output current is calculated from Thevenin's theorem. See Fig. 7.

**Fig. 7.** Thevenin circuit for temperature bridge of Fig. 5.

**Fig. 8.** Thermistor and bridge for high output voltage.

**Fig. 9.** Bridge for measurement in 300 C range.

ELECTRONIC DESIGN • April 30, 1958
high Thevenin resistance. However, it does serve
to demonstrate that large outputs can be ap-
proached by this type of circuit.

The examples given so far have been for room
ambients. At elevated temperatures the outputs
though less, are still extremely large compared
to similarly used components such as thermo-
couples. The upper temperature limit of com-
mercial thermistors in use today is approximately
500 C (932 F). Thermistors have been used at
higher temperatures, but for good stability it is
recommended that they be used below 500 C.

For use around 300 C the type 71A2 would
be approximately 2000 ohms. Assume now con-
struction of a 2000 ohm bridge using a 71A2 at
300 C.

At this temperature the thermistor's coeffi-
cient is about 1.5 per cent degree C. Using formula
(2) again and keeping the allowable self-heating
to 0.01 degrees C:

\[ E = \frac{(PR)^{1/2}}{2} = 0.0005 \times 2000 \]

Therefore the applied bridge voltage should be
0.63 volts (either ac or dc as the application may
warrant). Using formula (4) to find the output:

\[ V_o = \left( \frac{T}{T+B} \right)^{1/2} \]

\[ V_o = 2.52 \text{ mv} \]

Several added advantages are inherently
present in thermistor bridges. For example, the
thermistor may be located at remote distances
from the bridge itself since extension lead resis-
tance can be made negligible compared to the
thermistor resistance. Some other advantages are
the absences of cold junction compensation and
polarity observation which are always present
with the use of thermocouples.

A table will now be constructed showing com-
parative outputs of the thermistor bridges de-
veloped versus some of the more commonly used
thermocouples.

The thermistor bridge outputs indicated are
comparatively very high. However, the figures
shown are perhaps even more impressive when
it is recalled that they are drastically reduced by
the severe restriction that was placed on them to
achieve a readout accuracy of 0.01 degrees C.
Beads are made by placing exact drops of mix on two parallel platinum wires, above. Surface tension forms drops into little spheres which become beads when fired in a furnace, below. Mixture, shape of bead and spacing between beads determines characteristics.

THERMISTORS consist of a mixture of metallic oxides held together with a binder. All types of configurations are made from these mixtures. Discs and washers are formed on a pill press, rods on an extruder, and beads on special frames. Each forming operation is followed by firing or sintering to insure mechanical rigidity. A permanent crystal structure is formed. Photographs are courtesy of Fenwal Electronics, Inc.

Have Radar—Will Travel

"Paraballoon" antenna folds up, flies to the fight.
It's magnesium light.

Take a high-powered radar installation, and design it with magnesium so it can be assembled and disassembled easily, and toted around from place to place.

That's just what Westinghouse did when it developed the "Paraballoon" antenna for the Air Force. This highly mobile radar unit weighs just 1,730 lbs. compared to 10,000 lbs. for its comparable heavy metal counterpart. It can be taken apart by its crew in minutes, packed in 200-lb. containers, airlifted to a new location and put into action immediately.

Wondering why the "Paraballoon" antenna can do such a big job, yet weigh so little? The unit is constructed almost entirely of lightweight, rugged magnesium alloy. The reflector platform is magnesium sheet and extruded channels. The turning tube is a magnesium sand casting and the tripod is welded magnesium tubing. The radar reflector is a fully deflatable fiber glass balloon.

The "Paraballoon" antenna is one of the many examples of how the high strength-to-weight ratio of magnesium pays off in terms of saved weight in electronic equipment. For more information on magnesium in electronics contact the nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1416M.
Supramica ceramoplastics provide broader design scope for product engineers

Increased thermal endurance . . . total, permanent dimensional stability . . . better electrical properties . . . lower density and improved machineability of Supramica ceramoplastics bridge the design gap between organic plastics and conventional ceramics. The world’s most nearly perfect insulation, Supramica ceramoplastics allow product engineers to meet the requirements of today’s thermal problems.

There is no possibility of shrinkage, growth or age polymerization since the materials are completely inorganic, made with Synthamica* synthetic mica. Metal inserts molded in Supramica ceramoplastics cannot loosen during thermal cycling because coefficients of expansion are closely matched. Other desirable properties are high dielectric strength, radiation and arc resistance, low electrical loss, resistance to moisture, oil and organic solvents.

In thousands of military and critical industrial applications, Supramica ceramoplastics are contributing to better, safer, more reliable operation of electrical and electronic equipment.

Write for complete technical information.

Supramica* 560 — for temperatures over 500°C (932°F)

Supramica* 555 — for temperatures up to 650°F

Supramica* 500 — sheet and rod material for machining

*Supramica is a registered trademark of Mycalex Corporation of America. 560 and 555 and 500 are trademarks of Mycalex Corporation of America.

Synthamica is a trademark of Synthetic Mica Company, a division of Mycalex Corporation of America.

ACCELEROMETER

A fluid immersed sensing element moving precisely in a straight line makes possible the high accuracy of this accelerometer. Threshold sensitivity is better than $10^{-5}$ g. This means that when the accelerometer (circled) is attached to the index table shown, it has the ability to detect the gravity force produced by tilting its sensitive axis as little as 2 seconds of arc.

Three small metal cylinders are the basic elements of the device. The smallest internal cylinder is the acceleration sensitive element. This is immersed in a silicone fluid inside the next larger cylinder, which in turn is supported by bearings within the outer shell or case. The middle cylinder is caused to spin at 1000 rpm by a small external motor. This rotates the silicone fluid as well, and produces hydrostatic forces that exactly center the inner sensor away from adjoining walls, thus eliminating the need for bearings. Because no static friction is present, the slightest component of acceleration along the longitudinal axis is measured accurately.

Coaxial TR Tubes
For low frequency high power use

Designed for low frequency high power transmit-receive purposes, the TR860 utilizes a large metal-to-ceramic seal. Measuring 9 in. diam, the coaxial TR tube is cylindrical in shape with smaller window and seal areas than previous low frequency waveguide TR's. The reduction in size of these areas, plus substitution of ceramic for glass in the window, is stated to result in a more rugged yet lighter and smaller tube than conventional types.

Bolometer-Thermistor Mounts
Instantly replaceable

Both bolometers and thermistors may be replaced instantly in this series of matched bolometer-thermistor mounts. Replacement elements, available from stock, simply plug in without the use of tools, and require no adjustments.

The mounts feature low vswr of 1.5, without tuning, over the full waveguide band. Models 533 and 536 cover C to L band frequencies and may be used with both bolometers and thermistors. For frequencies from 5.4 to 10.0 kmc, models 531 and 532 are designed for use with bolometers, and models 541 and 542 for thermistors.

CIRCLE 52 ON READER-SERVICE CARD

Within the brief span of two decades, Keystone Carbon Company pioneered the development and commercial introduction of negative temperature coefficient resistance thermistors, and has become the principal supplier of these remarkable units to American industry, in the widest variety of forms.

It is an historic fact that the first thermistor shipment from Keystone, totalling 5000 units, occurred early in 1941 after three years of laboratory and pilot work. These units were for bomber intervalometers—a temperature compensation application. Later that year, 125,000 thermistors were supplied as sensing units for tank engine water temperatures—and the production flood began.

Since then, Keystone Thermistors have been supplied to the great names in American manufacturing for many measurement, control, and temperature compensation applications, including such uses as automobile temperature gauges, in meat probes for modern ovens, clinical thermometers, aircraft liquid fuel level indicators, and surge reducers in radio and TV circuits.

Today, some of the most interesting and promising new applications for Keystone Thermistors are in the very low temperature ranges, where stability and workable resistance values as low as —250°C are necessary.

Let us suggest that you bring your temperature sensing and compensation problems to KEYSTONE—thermistor headquarters for 20 years. Our full cooperation is always available.

A new Allison High Pass-Low Pass Filter permits direct reading of the frequency dial! The new filter, Model 420P, has separate High Pass-Low Pass Continuously Variable sections, allowing you to set up any band width within the range of 20 cycles to 20,000 cycles. For rapid, accurate analysis of noise, specify Allison Filters!

**ALLISON 420P FILTER FEATURES**

- Continuously variable frequency range from 20 cycles to 20,000 cycles
- 20 db attenuation in first octave
- Passive network • No power supply
- No vacuum tubes
- Dynamic range 140 db
- Designed for 600 ohms impedance
- Plug-in input-output transformers for other impedances
- Maximum input 2 volts
- Low loss—Approximately 2 db in pass band
- Low Pass Signals from d-c to cut-off frequency
- Minimum band width approximately one-half octave

Potentiometer

Linearity of ±0.3 per cent in production quantities.

Model 087 size 9 potentiometers are available with linearity accuracies to ±0.3 per cent in production quantities. Non-linear functions can be furnished. Specifications include a resistance range of 20 K, resistance tolerance of 2 per cent, and a standard electrical angle of 340 deg ±2 deg.

George Rattray Co., Dept. ED, 116-08 Myrtle Ave., Richmond Hill 18, N.Y.

CIRCLE 65 ON READER-SERVICE CARD

Printed Circuit Connectors

Bifurcation provides larger contact surface.

The Bellows Action contact for printed circuit connectors provides a redundant circuit, with two independent spring leaf contact actions for greater reliability. Coil spring action grip of the bifurcated contact clasps the printed circuit board over its entire contact area. A gold plated phosphor bronze spring retains tension when used with either undersized or oversized tolerance boards. The contact resistance is rated at less than 20 mv at 5 amp.

Wiring styles include eyelet lug for soldering, solderless wire wrap lug, taper tab solderless wiring, and contacts for dip soldering.

VIBRATION...yet normal operation

No—we don't use paint mixers to measure the vibration resistance of General Electric miniaturized sealed relays. But, it is a dramatic illustration of the punishment G-E hermetically sealed relays can—and do—wstand.

The best of laboratory equipment is used to measure this vibration resistance, and the results prove—General Electric voltage-calibrated Micro-miniature relays withstand vibration of 20 G's acceleration from 55 to 2000 cycles (.125 inch excursion from 10 to 55 cycles).

Excellent vibration resistance is just one of the many "plus" features—such as high- and low-temperature operation, high shock resistance, and rugged construction—you get with all Miniature, Sub-miniature, and Micro-miniature G-E sealed relays. Today, General Electric relays are proving their reliability on a variety of military and industrial electronics applications.

What's more, you get all of General Electric's complete line of standard-listed relays on only 3-week shipment from receipt of order—plus—immediate service on samples and prototypes.

For further information, contact your G-E Apparatus Sales Office—or—write to General Electric Co., Sect. 792-7, Schenectady 5, N.Y., for complete relay data. Specialty Control Dept., Waynesboro, Va.

NEW PRODUCTS

Recorder Amplifiers
Isolated differential input

DC μV signals as low as 20 μV can produce full scale deflection of a high speed 12 in. chart potentiometer in 1/4 sec or less with the Model 2HLA-7 preamplifier. This preamplifier has an isolated differential input, 20 cps frequency response, 1 μV recorded noise and drift, and gains as high as 100,000.

Applications for the preamplifier-recorder combination include low level thermocouple and differential thermocouple measurements, strain gage analysis, measurement of low output photocells, other processes where low level signals could be traced on a recording potentiometer.

CIRCLE 68 ON READER-SERVICE CARD

Differential Transformer
Explosion-proof model for 500 F use

This Atcotran differential transformer is explosion-proof and permits operation in temperatures up to 500 F. The unit measures 2-1/8 in. long by 1-1/4 in. od. Range is ±0.15 in. with a sensitivity of 0.5 mv output per 0.001 in. displacement per volt input at 400 cps. For a 20 v 400 cps input, the output is 0.001 amp to 500 ohm load for 0.05 in. armature motion.

TAPES YOU CAN

MINNESOTA MINING AND MANUFACTURING COMPANY

... WHERE RESEARCH IS THE KEY TO TOMORROW

TRUST because only Scotch Instrumentation Tapes assure absolute dependability inch after inch... reel after reel

You can't afford to compromise with accuracy, reliability and uniformity in critical recording work — instrumentation, computers, machine tool control and other technical applications. You need a magnetic tape of proven instrumentation quality, "Scotch" Brand Magnetic Tape.

These are precision tapes — engineered in the world's leading tape laboratories to meet your specific needs. You can trust "Scotch" Brand Instrumentation Tapes because they're made of only flaw-free materials and every reel put to more than 100 rigid quality control tests.

*These coefficients are unites and represent the change per % RH or degree Fahrenheit over the following ranges:

**Measured by recording 700 non-return pulses per inch on a 0.025" track. A reduction to less than 95% of normal signal amplitude constitutes a signal error. Zero errors are measured by selecting the tape unidirectionally. Each nnuol signal greater than 100% of normal amplitude constitutes a zero error. One error is inclusive of the minimum signal noise level of 0.0001 of the signal.

State your tape thickness, material, coating type, and manufacturing number. For the lowest price, tape is cut from the reel on which you specify the_thinning film. Manufacturer's claims are based on recording ten different 1/4" strips at the same temperature, and the results are averaged. Roll resistance is measured at 100% of normal signal amplitude and constitutes a zero error. One error is inclusive of the minimum signal noise level of 0.0001 of the signal.

**At optimum bias for each tape type.

Rate Meter

Fast quantitative analysis

Model 412, a premium log and linear multirange rate meter, is extremely useful for fast quantitative analysis. Applicable in high-speed scintillation and proportional counting systems, the unit simultaneously provides logarithmic and precision linear displays.

The five-decade logarithmic scale allows continuous accurate monitoring of activity levels varying over the widest ranges normally encountered.

Model 412 will drive any standard potentiometer or galvanometer-type recorders from both linear and log scales. Selectable by a ten-position front panel switch, the linear scale has ranges of 0 to 30 cpm and 0 to 1,000,000 cpm. A special five-cycle log scale provides a logarithmic range of 10 to 1,000,000 cpm.

Photo-Voltaic Cells

Silicon types with 20 μsec response

This series of silicon photo-voltaic cells has a response time of less than 20 μsec and very high lifetime expectancy. The cells operate, with no appreciable loss in efficiency, through a temperature range from -55 to +175 °C, with an effective spectror response range from 3000 to 8000 angstroms. Applications include punched tape and card readouts, programming controls, pinhole detection, remote switching controls, infrared sensing, and automatic counting.

CIRCLE 72 ON READER-SERVICE CARD
Lightweight and rugged for airborne applications

Hoffman ... leader in silicon semiconductor devices ... now offers this new line of sub-miniature ZENER REFERENCE ELEMENTS, specifically designed to maintain a constant DC voltage level under extreme temperature, shock and vibration conditions. This lightweight 8 grams. “Circuit commander” is ideal for use in applications demanding a stable and reliable voltage reference... in a case designed for miniaturized and printed circuit mounting.

Types INI530 and INI530A are available from stock to specifications per the chart above.

NEW PRODUCTS

Temperature Control
Utilizes magnetic amplifiers

Use of bi-stable magnetic amplifiers in place of relays in this temperature control extends operational life. Potting is used to bond together the entire unit. Proportional pulse modulation permits small deadbands in a high response system with good stability. When an error is detected at the edge of the deadband, short duration, full power pulses are applied to an actuator or valve motor. As the magnitude of the error increases the power pulses are of longer duration until finally power is applied to the actuator continuously.

The Garrett Corp., Dept. ED, 9851 Sepulveda Blvd., Los Angeles 45, Calif.

CIRCLE 74 ON READER-SERVICE CARD

Heat Dissipator
Press fitted over transistor

Designed to fit the JETEC-30 package, this device permits efficient heat dissipation for transistors. The finned jacket is made of black anodized aluminum alloy and can be press fitted over the transistor case without interfering with operation or servicing. Type 3AL-685 maintains a dissipation coefficient of Kr 0.28°C/mw.

The Birther Corp., Dept. ED, 4371 Valley Blvd., Los Angeles 32, Calif.

CIRCLE 75 ON READER-SERVICE CARD

Coaxial Cable
Highly stable to 200°C

Teflon jacketed, this low capacity, high temperature, miniature coaxial cable has a capacitance stability of 2 per cent from -65 to 200°C. Nominal outside diameter of the cable is 0.185 in.
The cable has a capacity of 10 μF per ft at 1 mc with 125 ohms at 1 mc characteristic impedance. Velocity of propagation is 81 per cent. Other electrical properties show attenuation of 10 db per 100 ft at 250 mc, and 16.5 db per 100 ft at 400 mc.

The Rex Corp., Dept. ED, Hayward Rd., West Acton, Mass.

**Galvanometer Amplifier**

60 ma output

System D is a 4-channel galvanometer amplifier package including power supply. It is suited for use with wire strain gages and other transducers, and will drive low-sensitivity, high frequency galvanometers. Features include a balanced input, high output of ±60 ma, phase sensitivity, high stability, low noise level, overload indicator and protector, and no operational delay when overloaded.

Allely Instrument Co., Inc., Dept. ED, 1091 Willis Mountain, Cumberland, Md.

**Potentiometers**

High resolution

Designed in 1-7/16 in. and 1-3/4 in. sizes, these potentiometers feature the availability of a wide range of special electrical features. Standard resolution for Model 1437 (1-7/16 in.) is 3900 wires, with a resistance range from 100 to 160,000 ohms. Model 1750 (1-3/4 in.) is available with resolution to 5000 wires, and with resistance ranging from 100 to 300,000 ohms. The standard linearity range for both units is 0.5 per cent to 0.1 per cent.

Giannini & Co., Inc., Dept. ED, Pasadena, Calif.

**GLASS-TO-METAL SEALS**

E-I glass-to-metal seals are available in hundreds of economical types of standardized designs. The complete line ranges from single lead terminals to miniature closures and color coded terminals. Specify E-I super-rugged compression type seals for critical military and commercial applications. Save time and eliminate custom sealing costs by using application-proven, standardized seals that meet practically every hermetic sealing requirement. Complete engineering data on the E-I Standard Line is contained in one helpful handbook. Write for your copy now.

Power supply users benefit from outstanding record of field performance

**LAMBDAA GUARANTEES POWER SUPPLIES FOR FIVE YEARS**

Retroactive to all Lambda Power Supplies purchased since 1953

Now Lambda gives you the strongest proof of consistent trouble-free power supply performance ever offered.

The unprecedented five-year guarantee is based on the excellent experience owners of Lambda power supplies have had with their equipment under the most grueling, heavy-duty service.

You are covered not only on new Lambda supplies, but also on all Lambda equipment you have purchased since 1953.

**See new Lambda Transistorized Power Supplies at I.R.E. Show**

They will be on display in Booths 2436 and 2438. You'll also want a close-up view of Lambda's Com-Pak series, for all needs up to 1.5 amperes. The Com-Pak models are real space savers. They need only 5¼" to 8¾" of front panel height, depending on the model.

**Send for latest catalog**

Your request, on your company letterhead, brings you complete data on all Lambda power supplies — rack, bench and portable.

**NEW PRODUCTS**

**High Power Loads**
Both coaxial and waveguide types

This line of high power loads in both coaxial and waveguide is stated to take more than 75 per cent of the full power capabilities of the line size used. Examples of power handling capabilities offered as follows: X-band 900 w average power overall length 9 in.; 1-5/8-in. coaxial line size, 1000 w average power, 12-1/2 in. length, and a 7/8-in. line size, 1000 w average power, 18 in. overall length.

Douglas Microwave Co., Inc.

- Tantalum Capacitors
  Ratings up to 150 wvdc

These low voltage tantalum foil capacitors consist of 15 sizes of both etched and plain foil tantalums, 0.125 od x 5/16 in. long to 0.375 od x 2-1/2 in. long. Voltage ratings are available from 3 wvdc to 150 wvdc and capacities from less than one µf to 6000 at 3 wvdc.

The units operate in the temperature range of -35 to +125 C. Featuring a solid cathode end construction, the capacitors are cased in silver or silver plate.

CIRCLE 84 ON READER-SERVICE CARD

CONTROL is first! Now—one step static control with switching reactors

No wonder Nikita looks worried. CONTROL has taken the strain off American industry’s pocketbook by cutting the cost of static control.

American engineers who want to make free use of power switching guided by digital logic can now take over, because CONTROL’s standard line of switching reactors give freedom of design and economy never before available.

First, one-step static control with switching reactors is so easy to operate it can be put to work in everyday sequencing and switching problems involving either a-c or d-c loads. Auxiliary equipment is eliminated by the basketful. Gone are all the preamplifiers, special power supplies, information-sorting single purpose logic units, and power switching relays. CONTROL’s one-step switching reactor does most of the job by itself.

Second, these units, in four nominal volt-ampere ratings of 15, 75, 150 and 300, have no relay contacts or moving parts to replace. Switching is by impedance change. Install them and forget them—no wear, no maintenance.

Third, each CONTROL reactor performs all logic functions—and, or, not, memory and time delay—through its multipurpose control coils. Signal source is derived typically from limit switches, push buttons, or photo-cells.

Fourth, each unit has a 10,000:1 switching ratio under nominal supply voltage conditions. High inrush currents are handled without difficulty.

To learn how CONTROL reactors work, and how they’ll fit your need for completely dependable, low-cost, versatile static control, write—and see why Nikita looks worried. CONTROL, Dept. ED-46, Butler, Pa. U. S. A.

Astron ' ' SAFETY MARGIN ' ' *
ELECTROLYTIC CAPACITORS
for transistorized and printed circuits

IMPORTANT DESIGN ADVANTAGES OF ASTRON EZ AND EX ELECTROLYTICS
- MINIATURIZED SIZE—LIGHT IN WEIGHT
- DESIGNED FOR MINIMUM LOSSES—LOW DRAIN
- LONG "SHELF" AND OPERATING LIFE
- HERMETICALLY SEALED
- RUGGEDLY CONSTRUCTED

Today's low-voltage transistorized and printed circuits demand capacitors with absolute minimum leakage and impedance. To meet these exacting needs, Astron Engineers developed new miniaturized EZ and EX Electrolytics for ambient operation up to 85° C.

99.99% pure aluminum foil is specially anodized by an exclusive process. The power drain is cut to a minimum. They are constructed to withstand extreme temperature changes and give reliable operation after periods of "long idleness."

Each electrolyte formula is scientifically compounded of special chemicals, selected for their high purity. Assembly steps are kept meticulously clean. The result: Safety Margin Construction, famous for its ability to withstand ripple currents, vibration, shock and wide temperature fluctuations. These hermetically sealed units are available in a broad selection of capacitance and voltage ratings.

Send today for further technical information... please describe your application; it helps us offer proper assistance to you... when special conditions require, we will design a prototype to meet your specifications.

NEW PRODUCTS

VSWR Amplifier
Battery-powered, transistorized unit

Battery-operated Model 441 is completely independent of line voltage deviations, and provides complete portability.

The unit features full sensitivity over the expanded vswr scale and eliminates the need for switching attenuation range when going from normal to expanded scale. The noise level, less than 0.02 µV equivalent, and amplifier gain remain the same in the expanded position. Sensitivity is 0.1 µV at 200 ohms, over the full scale.

Narda Microwave Corp., Dept. ED, Mineola, N.Y.

CIRCLE 87 ON READER-SERVICE CARD

Vibration Test Accessory
Pinpoints cause of failure

Designated Slip-Sync, this vibration test accessory automatically adjusts the flashing rate of stroboscopic lights to match the frequency of electromagnetic shakers in aircraft and missile testing. The vibrating component is watched in still or slow motion as it vibrates through the various frequencies to which it is subjected.

Chadwick-Helmuth Co., Dept. ED, Monrovia, Calif.

CIRCLE 88 ON READER-SERVICE CARD
Oscilloscope
Plug-in 4-channel instrument

Through the use of plug-in features for individual pre-amplifiers, sweep generators, and marker-calibrator, this wide-band oscilloscope combines the advantages of true four-channel oscillography. Known as ETC Model K-470, the instrument handles oscilloscope applications from dc to 5 mc.

Five pre-amplifiers form an integral part of the instrument and may be used in any combination on each of the four channels. The ETC Model K-470 is one of the first scopes to use a special square face, four-gun cathode ray tube.

Electronic Tube Corp., Dept. ED, 1200 E. Mermaid Lane, Philadelphia 18, Pa.
CIRCLE 89 ON READER-SERVICE CARD

Pulsed Oscillator
Stable high power output

Model PG-650 is a variable frequency pulse modulated r-f source for applications requiring high power output as well as stability. The principal use is in measuring various parameters of ultrasonic delay lines, whose high initial insertion loss and operation at low impedance levels usually present difficulties.

The output of a delay line (60 db into 50 ohms) can be shown at r-f using only the vertical amplifier of an oscilloscope. A second feature is that it can cascade two delay lines without an intermediate amplifier.

Arenberg Ultrasonic Lab., Inc., Dept. ED, 94 Green St., Jamaica Plain 30, Mass.
CIRCLE 90 ON READER-SERVICE CARD

the new KEMETAL electro-less process of copperplating

forms a close, tightly adhering chemical bond

The KEMETAL process deposits copper on ceramic (or any other) surface UNIFORMLY, directly out of solution. Complex or irregular surfaces are never a problem as with ordinary electroplating.

Forming a close, tightly adhering chemical bond that is not lost in soldering, the process eliminates critical soldering time and temperature worries.

The copper, as applied in this process, has 100 times less migration activity between electrodes than silver in electronic circuit applications, assuring a longer life of high dielectric effectiveness.

the KEMETAL process is now used in the manufacture of RI-caps... CERAMIC DISC CAPACITORS and FEED-THRUS.

NEW! From the Laboratories of General Ceramics

50 MIL O.D. Memory Cores for Transistorized High Speed Memories

These new 50 mil O.D. cores are now available in General Ceramics S-4, the material that has proven so successful in such vitally important systems as the SAGE computer. Switching time is less than one microsecond with 550 ma full drive. At recommended operating conditions, the "ONE" output voltage is greater than 60 millivolts; the "ZERO" output voltage is less than 6 millivolts. Cores are provided in two quality levels, to .015 AQL and to 6.5 AQL. Dimensions are .050" O.D., .030" I.D. and .015" in height, all with tolerances of ±.002". General Ceramics has designed and built special equipment for core testing to insure that each unit meets established electrical properties. 50 mil O.D. cores are supplied in production quantities in two quality levels. Parts are shipped according to MIL Specification 105A to 0.015 AQL or 6.50 AQL. For complete information on this core write General Ceramics Corporation, Keasbey, New Jersey, for Bulletin 326; address Dept. ED.

NEW PRODUCTS

Hydrogen Thyratrons
High reliability, long life

For radar and other high-power pulse modulators, Genalex hydrogen thyatrons offer more reliable operation and greatly increased life through a new replenisher system, controlled by an integral barreter and thermistor. The replenisher generates hydrogen by means of a heater surrounding titanium hydride pellets and prevents tube failure due to gas clean-up.

A barreter in series with the replenisher heater keeps the gas pressure constant. A thermistor in parallel with the heater maintains constant replenisher temperature over an ambient range of -25 deg C to +70 deg C and reduces warm-up time and anode delay time drift.

British Industries Corp., Dept. ED, Port Washington, N.Y.

CIRCLE 93 ON READER-SERVICE CARD

Pulsed Oscillator
Miniature high power unit

The A-12 miniaturized high power 2 kw output pulsed oscillator cavity is designed for aircraft, beacon, and missile applications. The unit measures 5.75 in. in the tunable model and only 4.9 in. in the fixed frequency version while only 1.75 in. in diameter.

Designed to sustain rugged treatment utilizing the GL 6442 ceramic triode, the A-12 can be tuned in excess of 200 mc in the S band.

Atomitron, Inc., Dept. ED, 169-25 Hillside Ave., Jamaica, N.Y.

Microwave Circulator
Compact broadband unit

Model RX 810 C is a broadband, compact, four port circulator utilizing the principle of Faraday rotation of the plane of polarization of microwave energy.

The unit is 4-15.16 in. long and operates over the band 8.4-10.2 km with a minimum of 13 db isolation and 0.35 db insertion loss. The circulator can be pressurized to 30 psig.

Rantec Corp., Dept. ED, Calabasas, Calif.

Chokes
Encapsulated types for 125 C use

A family of epoxy encapsulated chokes, covering a range of inductances from .01 µh to 200 µh is available in various configurations. One popular type features a flat side for mounting on printed wiring boards with axial leads. Additional leads are provided for mechanically securing heavier components.

For production testing and process control
CMC announces the Model 620A

ELECTRONIC GO-NO-GO GAUGE

Here's an interesting new instrument from CMC with a host of applications in production testing and process control.

The Electronic Go-No-Go Gauge monitors any control or limiting situation which can be stated in terms of frequency. For instance, in electronics for unskilled workers can tune oscillator circuits, filter networks, etc., with great accuracy. Frequency stability and comparison checks can be made quickly and easily. In mills and factories producing a continuous flow of goods such as steel, rubber, paper, the device can be used as a material flow controller keeping the output in tune with the input, preventing line buckle and stretch-out. In chemical and agriculture processing, the Model 620A can be serve as a pressure or liquid flow regulating indicating system. Wherever motor speed control is a problem, the Model 620A will hold the speed within preselected limits.

How it Works
In operation, the unknown frequency generated by either the unit under test or one of the many types of transducers on the market is applied at the input. Upper and lower frequency limits are selected by setting the control knobs on the front panel. If the unknown frequency falls below the lower limit, a red "low" lamp lights. Equal to or above the higher limit, a red "high" lamp lights. Within either limit, a green "in limits" lamp lights. Relay contact closure for external control occurs at each lamp condition.

Actual input frequency is displayed on decades. Remote visual monitoring can be obtained with CMC's new Inline-Inplane Readable Readout. Use of CMC's new fast printer provides a permanent printed record.

Like all CMC instruments, the new Model 620A features uniform construction for structural strength and low weight.

KEY SPECIFICATIONS

FREQUENCY RANGE | 1 - 40,000 cps
INPUT REQUIREMENTS | .05 mV min. 1 - 40,000 cps
| .707 mV min. 1 - 10 cps
ACCUCCY STABILITY | ±1 count ± stability
| 0.1% (Normal power line stability)
TIME BASES | Crystal time base optional.
| 0.1 sec. and 1 sec. (10 sec. optional)
DISPLAY TIME | 4 digits (5 digits optional)
| Automatic: Continuously variable 0.1 to 10 seconds.
| Manual: Until reset
INPUT IMPEDANCE | 0.5 megohms and 50 mmfd
PRICE | $1120.00 f.o.b. factory

Flat Cable
Can be solder dipped
A lightweight, flexible, multi-conductor flat cable called Polystrip is available. Insulation is a polyester which can be quickly stripped and the cable solder dipped. The cable is rated at 85 C continuously, and is available in widths up to 31 conductors. Each conductor is conservatively rated at 1 amp in free air at 25 C.
International Resistance Co., Dept. ED, 401 North Broad St., Philadelphia 8, Pa.

Remote Control System
Combines accuracy with high torque
The Electrolink model 60 is a closed-loop remote positioner designed specifically for industrial applications requiring fast response, high output torque, and high accuracy. The unit consists of a combined controller-amplifier and a servo drive.
The output shaft, driven by the high-response powder clutch, follows movement of the manual control with accuracies better than 0.25 deg. At maximum excitation, servo output torque is 250 in. lb. High gain and low-inertia drive permit the system to reach maximum speed in 0.020 sec.
Installation problems are simplified by modular construction, permitting the control to be panel-mounted away from the amplifier.
Lear, Inc., Dept. ED, P.O. Box 688, Grand Rapids, Mich.

High-Pot Programmer
Applies voltages at controlled rate
The function of model 1102 is to program the line voltage fed to a high-pot tester, thus producing a system in which test voltages are applied to components under test at a uniform controlled rate. The programmer prevents equipment damage due to accidental output surges, and assures that each component is given an identical, precisely controlled test.
Jackson Electronic and Mfg. Co., Dept. ED, 895 Johnston St., Akron 6, Ohio.
SCHEDULE THESE TWO IMPORTANT ISSUES NOW

1. TRANSISTORS

- Transistors
- Materials for Transistors
- Components for Transistors
- Test Equipment for Transistors

Circuit and equipment designers will be on the lookout for Electronic Design's 6th Annual Transistor Data Issue—complete with the Transistor Data Chart, only complete transistor data source of its kind in the industry. This issue is read, and re-read, then filed for reference. You can depend on new highs in readership, greater response to your advertisements (last year 5,632 engineers responded), higher return for your advertising dollar. Be sure your company takes advantage of this once-a-year opportunity in the TRANSISTOR DATA ISSUE. Forms close June 13th.

Transistor Issue—Closing Date June 13th

2. DIODES

Semiconductor diodes, their increasing importance, application, and use will be the subject of Electronic Design's second feature issue in July. For the first time, manufacturers of diodes and their associated components, materials, and hardware, test equipment, etc. will be spotlighted. Special editorial surveys, data charts, characteristic curves, and availability lists will add to the regular editorial packaged in this issue. It's an issue you will want to include in planning your 1958 insertions.

Diodes—Feature Report—Closing Date June 27th

NEW PRODUCTS

Nylon Jack
Self-locking into chassis

The Pushlock molded nylon-tip jack requires no threads, nuts or lock washers. When the fluted nylon body is pushed through a 1/4 in. chassis hole, the flutes compress and expand to provide positive holding action that requires approximately a 50-lb pull to release. Contact pressure and low resistance are provided by a heat treated, silver-plated beryllium copper contact.

Whitso, Inc., Dept. ED, 9338 Byron St., Schiller Park, Ill.
CIRCLE 104 ON READER-SERVICE CARD

Relay
Rotary action

The HG-2SMP series relay is a plug-in unit with an asbestos filled melamine socket designed specifically for performance exceeding standard socket units. Rotary action and rugged construction make the relay suitable for reliability and rapid interchangeability.

Contacts are rated up to 5 a and 250 v with coil operating voltage of 6 to 115 v ac or dc. Contact arrangement is 1 or 2 pole double throw.

Sockets are available with several types of gold plated terminals to mount above or below the chassis.

Hi-G, Inc., Dept. ED, Bradley Field, Windsor Locks, Conn.

New GENISCO flight control accelerometer permits check out of system reliability prior to, or during, flight operations

This newest Genisco instrument is a modified version of the unusually rugged, military certified Model DDL Accelerometer. The Model DDL was developed specifically to withstand severe vibration and stress in high-speed aircraft, guided missile and fire control system applications. It is now in use on many of the nation's fastest operational jet fighter aircraft.

In the new Model DDL two miniaturized solenoids have been added to the basic design of the Model DDL. When actuated, these solenoids displace the mass through its full range permitting rapid, functional tests of system reliability prior to, or during, flight operation.

Only brief specifications of the Model DDL are given below. Copies of Technical Data Sheets giving complete specifications will be sent upon request.

Because most parts of the new Model DDL are interchangeable with the Model DDL now in high-quantity production, price and delivery are particularly good.
For Ultra High Frequency Insulation

**REXOLITE 1422**

In cast rods of diameters to 6" and plates up to 36" x 36", from .031" to 1½" thickness.

**REXOLITE 1422 CHARACTERISTICS**

- Withstands high temperatures — to 400° F.
- Does not exhibit cold flow.
- Has low dielectric constant and power factor.
- Specific gravity of 1.045-1.050.
- Is strong and rigid with good tensile and impact strengths.
- Unusual chemical inertness permits its use where others fail.
- Readily machinable to close tolerances.

**WHERE PERFORMANCE PLUS PRICE IS A FACTOR**

**REXOLITE 2200**

UHF insulation in thermosetting sheets 36" x 36". Thickness .031"-.125" thick

CIRCLE 111 ON READER-SERVICE CARD

**Electrolytic Capacitors**

High voltage and capacity ratings

For high μf applications such as bulk capacitance requirements, these Alumalytic capacitors are rated from 30,000 μf at 10 v dc to 100 μf at 450 v dc and will operate from -20 to +65 C. The capacitors are manufactured with diameters of 1, 1-3/8, 2, and 3 in., and with a length of 4-1/8 in. The 1 and 1-3/8 in. diameter units are available in case lengths of 2, 2-1/2, 3, 3-1/2 in.

The principal construction feature of this capacitor is the use of 99.99 per cent pure aluminum foil anodes in every rating. This type of pure aluminum permits increased shelf and operating life and reduces leakage current.

AHEAD AGAIN...

U. S. Radium's Newest Instrument Dial

A current problem in integral instrument lighting is that of obtaining, at reasonable cost, a dial for a particular unit which will light within the brightness ratio spec of MIL-L-25467A. Since different instruments will have different lighting systems and will require different dial configurations and indicia, the dial contractor must be able to vary the opacity of his dials in order that the finished instrument assemblies will light to MIL spec, regardless of the internal light levels and the number and position of the lights.

U. S. Radium's new production process for MIL-L-25467A dials permits the variation of the opacity factors of the background and indicia within wide limits, to provide a compatible instrument-dial assembly. It also allows piece-to-piece uniformity which excels conventional methods for meeting this spec, and at lower unit cost. These advantages, plus the availability of U. S. Radium's light engineering service during the formative stages of light housing design, provide a foolproof working method for eliminating light engineering headaches, cutting costs and speeding delivery.

For information, contact Department D4
This stable, all transistorized Gaussmeter operates on the Hall effect and provides a conservative accuracy of ±3% over nine full-scale ranges: 0-100, 200, 500, 1 K, 2 K, 5 K, 10 K, 20 K and 20 K+ gauss, using a single probe. Two standard Alnico V reference magnets having ½% accuracy are supplied. Unit is housed in an aluminum case, weighs 12 lbs. and operates from 115-volt, 50-400 cps line. Price $420.

**Magnetreater**

Model 889A de-magnetizes saturated magnets to any desired level of flux. Provides a precisely controlled method for rapidly treating permanent magnets, including the new core-type instrument mechanisms. Used with Model 206A Booster Unit or Model 107A Magnet Charger. Over-all size is 8" x 10" x 7". Weight 24 lbs. Price $163.

**Standard Magnets**

Laboratory standard fixed gap reference magnets having flux densities from 100 to as high as 20,000 gauss are now available. These units are fully stabilized magnetically, mechanically and thermally and are used to calibrate fluxmeters and gaussmeters for engineering or production testing. Certification supplied for each magnet.

Performance of all models is rigidly guaranteed. Prices are net f.o.b. Boonton, N.J., and subject to change without notice.
NEW LITERATURE

Slip Ring Assemblies
"Design Considerations for Miniature Slip Ring and Brush Assemblies" is a 32-page pamphlet. Photographs and drawings are included. Poly-Scientific Corp., Blacksburg, Va.

Coaxial Terminations
This illustrated bulletin sheet describes a line of coaxial terminations with type BNC or TNC, male or female connectors. Stoddart Aircraft Radio Co., Inc., 6644 Santa Monica Blvd., Hollywood 38, Calif.

Wirewound Resistors
Bulletin CB-3 describes and illustrates a line of axial, radial, and lug type precision wirewound resistors. Winding techniques, wattage range and temperature range are included. Kelvin Electric Co., 5907 Noble Ave., Van Nuys, Calif.

Microwave Components
This 48-page catalog describes over 300 different types of microwave waveguide components, test equipment, and pressure windows. Designated Catalog 58CP, it includes operating characteristics, performance curves, application data, outline drawings, dimensions, and prices of components in the 1.12 km to 90.0 km frequency range. Photographs of each product type are included. Microwave Associates, Inc., Burlington, Mass.

Aircraft and Missile Testers
This catalog describes a line of aeronautical and missile testing equipment. Featured in addition to a line of hydraulic system testers are many electrical devices. These include power supplies, generator testers, panel meters, and other equipment to test almost any electrical assembly that flies. Sun Electric Corp., Harlem and Avondale, Chicago 31, Ill.

Synchros
This catalog sheet presents the salient characteristics of synchros, servomotors, resolvers, motor tachometers, and tachometer generators in production. The information is arranged for easy reference, and forms a useful key to the more detailed information contained in the sheet. Muirhead Instruments Inc., 677 Fifth Ave., New York, N.Y.
R-F Filters

This 4-page catalog lists custom r-f filters. Variations in size, shape, voltage, and current ratings are allowed without extra cost for this custom order service. All-Tronics, Inc., 45 Bond St., Westbury, N.Y.

Impregnated Fibre

Bulletin V-58 is a 4-page folder describing a low-cost intermediate insulation material made of resin impregnated vulcanized fibre for use in many electrical and bearing applications. Typical applications are given for the material, which is available in the larger 43 x 76 in. sheet size. Tables and charts give mechanical and dielectric strength compared with those of other materials normally used for high-volume electrical and structural applications, together with physical properties. Continental-Diamond Fibre Corp., a subsidiary of the Budd Co., Newark, Del.

Circuit Analysis

This brochure titled "Modern Testing Methods" describes how this company's analyzing equipment can be utilized by various manufacturers to test wiring systems in all phases of production. It points out how this same testing system, as used by the manufacturer, may be passed on to the military as support equipment to test electrical systems of aircraft, missiles, etc., at maintenance and overhaul bases, thus allowing the manufacturer and the military to standardize on like test equipment. DIT-MCO, Inc., 911 Broadway, Kansas City, Mo.

Film Capacitors

Polystyrene, polyethylene, teflon, and Mylar dielectric capacitors appear in a 6-page illustrated catalog. The folder also lists a line of high voltage packaged power supplies. Electrical characteristic data, physical specifications, related part numbers, and prices are shown for all types listed. Film Capacitors, Inc., 3400 Park Ave., New York 56, N.Y.

Digital Voltmeter

The operation, features, and specifications of a dc digital voltmeter are discussed in the four pages of Bulletin 19-2. Also described are accessories that may be added to permit the measurement of ac, ohms, and ratios, to allow scanning multiple inputs, or to drive typewriter and punched tape units. Kin Tel, Div. of Cohn Electronics, Inc., 5725 Kearny Villa Rd., San Diego 11, Calif.
Torque as low as 0.003 ounce inches achieved by Giannini in MICROTORQUE* and MINITORQUE* Precision Potentiometers

For extremely sensitive instrument applications where minimum torque is essential, specify Giannini Microtorque and Minitorque precision potentiometers. Highly reliable performance under the most rugged operating conditions is assured by Giannini's care for detail and production crafting.

By using sapphire jewel bearings ... and precision ball bearings in certain Minitorque models, these 1 inch diameter instruments effect an unusually low coefficient of friction.

Available in 12 standard linear wiring types, the potentiometer output can, on special order, be designed to perform to a wide range of natural or empirical functions. All models employ non-corrosive precious metal windings and contacts ... thereby permitting light brush pressures and ensuring long noise-free life.

Dependability, reliability, and ten years proven application success are your benefits, when you use Giannini Microtorque and Minitorque potentiometers—precision instruments "crafted with care."

For additional information, please write for Bulletins 85111 and 85151.

SPECIFICATIONS:

Torque .................. 0.003 to 0.008 oz. in. depending on resistance and wiring type. (Sleeve bushing Minitorque 0.025 oz. in.)
Resistance Range .......... 100 to 100,000 ohms.
Linearity .............. ±0.5% (±0.25% on special order)
Power Rating .......... 1.63 watts @ 25°C.
Shaft Diameter .......... Microtorque, 0.031 in.,
                       Minitorque, 0.125 in.
SPECIAL TERMINALS, SAPPHIRE-TO-METAL SEALS AND MAGNETRON WELLS AVAILABLE

High alumina ceramic and metal parts are brazed together to form a high-strength, long-life, molecular seal.

Stock sizes for up to 100 KV-DC operating voltages available for short delivery.

At all times, VECO strives to improve its product for the benefit of its customers.

NEW TECHNICAL CATALOG AVAILABLE
8th edition — containing pertinent data and condensed engineering specifications covering over 250 VECO stock items.

Send for the interesting, informative series entitled, "MEET THE VECO THERMISTOR" •

CIRCLE 146 ON READER-SERVICE CARD

Continuous electroplating methods permit coating of many metals on to wire (or ribbon) in specified thicknesses of plate . . . This very flexible operation makes it possible to designate a desirable base or precious metal with a coating of another metal for its own particular characteristics. In our laboratory Tungsten wire as small as .0015" has been electroplated with Gold. . . . New combinations of plating on wire are being developed by our research staff from time to time. Your inquiry is invited.

Consult us, without obligation, about your specific wire problems. Write for list of products.

CIRCLE 147 ON READER-SERVICE CARD
NEW LITERATURE

Precision Potentiometer Table 148

A handy precision potentiometers table in 8-1/2 x 11 in. page size to fit the data file or loose-leaf binder, is available. The table lists seven single-turn and one multi-turn types, with dimensions, resistance values, tolerances, resolution, ratings, rotation, tandem groupings, torque, taps, weight, bearings, and other data. At a glance the designer or engineer can select the precision potentiometer that best meets his particular requirements. Clarostat Mfg. Co., Inc., Dover, N.H.

Digital Pulse Decoder 149

A 12-page engineering manual has been issued to describe a digital pulse decoder and its several applications. With diagrams, the text explains the use of the selector in both ac and dc circuits. It specifically discusses remote supervisory control, telephone, telegraph printer, and mobile radio applications. Photographs and a list of specifications round out a description of the instrument itself; and operation, code settings, and installation are separately discussed. Electrical Communications, Inc., 765 Clementina St., San Francisco 3, Calif.

Time Rate Indicator 204

Bulletin 501A-B discusses the applications of a 10 mc time-rate indicator which measures frequency, the interval between pulses and period or averaging period, determines the ratio between two frequencies, and counts pulses per unit time. The 4-page illustrated brochure explains the features, functions, and advantages of the unit as it is used in various types of electronic circuits. Laboratory for Electronics, Inc., 75 Pitts St., Boston 14, Mass.

Batteries 205

This 20-page three color catalog illustrates and presents information on all types of a company’s dry cell batteries. Specification charts list each type of battery on separate pages. Also included, on fold-out page, is a cross reference chart of “Comparative and Interchangeable Numbers by Brands.” Marathon Battery Co., Wausau, Wis.

Potentiometer 206

Details of the series 7600 precision potentiometer are covered in Data Sheet 1273. In addition to dimensional drawings and descriptive text about the 10-turn, 1-13 16 in. diam potentiometer, the four-page data sheet now includes a table of coil characteristics for resistance values ranging from 350 to 450,000 ohms. Beckman Helipot Corp., Newport Beach, Calif.

select the right pilot light...

Johnson pilot lights immediately available for original equipment or in-the-field replacement!

Save valuable specification time by selecting your panel indicators from Johnson’s “preferred” line. This group contains over 47 separate assemblies carefully selected from Johnson’s standard line by many of the nation’s top design and development personnel. Available in a wide variety of types, these “preferred” units are immediately available at parts distributors throughout the country, for original equipment or in-the-field replacement. Write for your free copy of Johnson’s newest pilot light specification catalog—see how easy it is to select the right pilot light...fast!

Available types include: continuous indication types; models for high and low voltages; incandescent bulbs; standard and wide angle glass and lucite jewels in clear, red, green, amber, blue or opal. Specials, including these meeting military specifications are also available in quantities.

Beckman Helipot Corp., Newport Beach, Calif.
Research Activities

The activities and fundamental research program are described in a 12 page booklet just released. Subjects covered include the SAGE system, heavy radar, memory devices, transistorized digital computers, scatter communications, AEW, and systems analysis. M.I.T. Lincoln Laboratory, Box 24, Lexington, Mass.

Polyethylene Sheath

The bulletin, describes the advantages of polyethylene sheathing compound, its specifications, and applications. Rating, scope of use, conductor construction, insulations, and shielding of available sheathed cables are detailed. The sheathing material passed industry (IPCEA) tests for ac and dc voltage and corona level.

Tables show the insulation and sheath thicknesses for 5001-9000 v (single conductor, grounded neutral), 3001-5000 v (single conductor, grounded or ungrounded), 5000-9000 v (single conductor, ungrounded neutral), and 15,000 v (single conductor, ungrounded neutral). AWG or MCM wire size, standing and nominal od in inches are also given in each table.

The four page bulletin, 8-1/2 by 11 in., is punched for notebook insertion. Rome Cable Corp., Rome, N.Y.

Coils, Connectors, Clips

Custom designed for use in electrical and electronic applications. Made from all metals to specific mechanical and electrical requirements. Special coatings where desired. Automatic equipment to produce varieties of shapes economically. Write for handy "Picture Book of Springs."
Machlett Laboratories, Inc. offers the designer a new forced-air-cooled, shielded grid triode designed primarily to operate as a switch tube in hard-tube pulse modulators in radar applications. Ruggedly constructed electrodes of the ML-6544 are of such a design as to provide electron beaming essential in keeping grid current to a minimum. This, in addition to the increased heat dissipation capabilities of the rugged control-grid structure, reduces grid emission to a negligible quantity.

The following tentative ratings apply:

### Electrical Characteristics
- Filament Voltage: 6.0 Volts
- Filament Current: 60 Amps

### Maximum Ratings
- Peak Plate Voltage: 25 kv
- D-C Plate Voltage: 20 kv
- D-C Grid Voltage: –400 Volts
- Peak Positive Grid Voltage: 1500 Volts
- Peak Cathode Current: 75 Amps
- D.C. Plate Current: 100 mA
- Grid Dissipation: 1000 watts
- Plate Dissipation (150 cfm @ 0.8" water): 45 watts

*Sufficient air cooling must be provided to keep glass seal temperatures no more than 175°C under all conditions of operation.

NEW AUTOMATIC CIRCUIT TESTING BRIDGE

**ROTOBRIDGE**

- 99 test positions • one test per second • tolerances of 5, 10 and 20% • wide component range • stabilized circuitry and simple, tamper proof operation.

**AUTOMATIC, SEQUENTIAL, CIRCUIT TESTING BRIDGE FOR CIRCUITRY AND COMPONENTS WITH EASILY PROGRAMMED INTERNAL STANDARDS**

Improve your quality control and save time and money by automatically testing circuit assemblies in seconds with the all new Model 1020.

**FEATURES:**
1. A quality switch with more than a decade of telephone industry development.
2. Easily programmed standards and tolerance drawers.
3. Stabilized circuits to insure accuracy of measurements.
4. Audible and visual alarms for rejects or end of testing cycle.
5. Easily read "Nixie" tubes indicate digitally the circuit under test.

NEW LITERATURE

Coaxial Components

Coaxial components are cataloged in a 28-page booklet. Attenuators, filters, terminations, power dividers, crystal mounts, stub tuners, and miniaturized components are among the items listed. The catalog covers the operation theory of each product. It also presents application and performance data and mechanical electrical specifications. Microlab, 71 Okner Pkwy., Livingston, N.J.

Insulating Tubing

A selector card for insulating tubing and sleeving has been issued. It has a size gage and more than 40 tubing samples. Technical data on the 8-1/2 x 11 in. card includes dielectric strengths; temperature ratings; applicable NEMA, ASTM, and MIL specifications; flammability; oil resistance; flexibility; abrasion resistance; and resistance to potting. Suflex Corp., 33-38 87th St., Woodside 77, N.Y.

Meters

An illustrated catalog features a full line of electrical indicating instruments. Covered are dc microammeters, dc milliammeters, dc ammeters, dc voltmeters, thermocouple rm ammeters, db, vu, and rectifier type ac instruments. Ruggedized types, commercial types, and types that conform to MIL-M-10304 are described. Sun Electric Corp., Harlem and Avondale, Chicago 31, Ill.

Precision Resistors and Networks

A fact-packed 8-page catalog covering a complete line of custom-made precision wire-wound, encapsulated resistors and rugged, hermetically sealed resistor networks is now available. In this comprehensive, compact catalog are several easy-to-read charts and graphs, and many illustrations, drawing, and specifications pertinent to the life-tested resistors and networks. General Resistance, Inc., 577 E. 156th St., New York 55, N.Y.

Epoxy Pumps

The operation of automatic epoxy pumps which mix, meter, and dispense two-part resins is explained in a recent brochure. Specifications and performance data are given for ten pump models. A technical advisory service which includes custom compounding is described in the same brochure. H. V. Hardman Co., 571 Cortlandt St., Belleville 9, N.J.

Epoxy Thinner 167

Expanded data sheets on the properties and applications of epoxy resin flexibilizer NC 513 are available. The flexibilizer is used for epoxy coatings, encapsulation of electrical components and electrical potting compounds, tooling resins and plastic forming molds, epoxy resin adhesives, patching and splining compounds, and glass-reinforced epoxy resins. Minnesota Mining and Mfg. Co., 500 Doremus Ave., Newark 5, N.J.

High Temperature Wire 168

"Kulgrid 28, Nickel Clad Copper Wire" describes the chemical composition, mechanical properties, conductivity, and resistivity of a wire developed for high temperature use in electrical and electronic equipment. The technical bulletin also contains the results of comparative laboratory tests made on the resistivity of the wire at elevated temperatures. Sylvania Electric Products Inc., Warren, Pa.

Nonlinear Pots 169

With graphs, Technical Bulletin 10 shows the magnitude of resulting error due to external loads on several nonlinear potentiometer functions. The 4-page brochure also indicates a unique approach to nonlinear design and explains compensated winding procedure for any nonlinear functions. Technology Instrument Corporation of California, 7229 Atoll Ave., North Hollywood, Calif.

Miniature Pulse Transformer 170

Information about the ES-3, a subminiature pulse transformer for use in transistor circuits, is presented in a 1-page bulletin. The model is a spherical form encapsulated in epoxy resin to a maximum diameter of 3/8 in. for simplified mounting on printed circuit boards. The text covers the unit’s features, construction, and ratings. A photograph shows its actual size. Pulse Engineering, Inc., 2657 Spring St., Redwood City, Calif.

Vacuum Systems

A 16-page product summary and price list shows a complete line of standard and custom high vacuum components, equipment, and systems. Mechanical and diffusion pumps, gauges, valves, analytical apparatus, furnaces, freeze-drying equipment, and leak detectors are among the items listed. For a copy of this catalog write on company letterhead directly to NRC Equipment Corp., 160 Charlemont St., Newton 61, Mass.
AMERSIL service is keyed to your requirements. Here, at the primary source for fused quartz and silica ware of critical purity, several specially developed production processes are used—each providing an end product suited precisely to certain types of fabrication and use. Delivery is prompt. Standard apparatus, crucibles, trays, cylindrical containers and tubing (up to 25" diam.) are available for prompt service. Amersil engineers will be glad to assist in developing special equipment for your requirements. Your inquiry is invited.
new complete line of

GERMANIUM GOLD BONDED DIODES

GENERAL TRANSISTOR IS NOW MAKING GERMANIUM SUBMINIATURE GOLD BONDED DIODES

You may be assured that this new product line has the same high quality and reliability that has made General Transistor the Fastest Growing Name in Transistors. Experienced design engineers, quality materials, proven production techniques, and strictly enforced quality controls are your guarantees.

These diodes have been designed for computer, industrial and military applications where high reliability is of prime importance. They are hermetically sealed in a glass case with tinned leads. Their rugged construction makes them resistant to humidity, shock and vibration, and impervious to extreme environmental conditions.

Write today for Bulletin GD-10 showing complete specifications, diagrams and other engineering data.

NEW LITERATURE

Miniature Relays 174

Over 325 subminiature relays are described in a 12-page booklet. Designed for missile, airborne, and industrial equipment, the relays meet and surpass Mil-5757A, B, and C and Mil-E-25018 (USAf). Complete descriptions of the units include contact and vibration ratings. Photographs and diagrams illustrate the booklet. Radio Corporation of America, Commercial Electronic Products, Camden 2, N.J.

Batteries for Aircraft 175

A line of production batteries for unmanned aircraft and missiles, and 11 for manned aircraft, are described in this recently published bulletin. The bulletin covers nominal capacity, open circuit voltage, normal discharge voltage, maximum charging voltage, charging rate, maximum current conditions at 70 deg F, weight, battery dimensions, and case material. Yardney Electric Corp., 40-50 Leonard St., New York 13, N.Y.

Thyratron Grid Control 176

Bulletin 101-L features a packaged thyratron grid control for motor and generator controls, regulated power supplies, servo systems, and process control. The 4-page pamphlet presents circuit details, mechanical features, and typical applications. It is illustrated with graphs, schematics, and photographs. VecTrol Engineering Inc., P.O. Box 1089, Stamford, Conn.

Electronic Parts Catalog 177

Listing over 27,000 items, this 404 page catalog describes a line of electronic parts and equipment. The catalog features 192 pages in rotogravure and 4-color covers.

The catalog emphasizes equipment for industrial maintenance, research, and production requirements. There are detailed listings of standard and special purpose electronic tubes, test instruments, voltage stabilizers, transformers, resistors, capacitors, printed circuit components, new transistors, rheostats, relays, switches, rectifiers, fuses, tools, wire, cable, photo-electric components, two-way radio telephones, sound powered telephones, counters, program clocks, timers, batteries, sockets, generators, power supplies, and a wide variety of other electronic components.

Also included in the bulletin are audio equipment and test equipment kits. Allied Radio Corp., 100 N. Western Ave., Chicago, 80, Ill.
TELL YOUR PERSONNEL MANAGER ABOUT ELECTRONIC DESIGN’S "CAREER'S SECTION"

If your company is trying to attract skilled electronic design, development or research engineers, tell your Personnel Manager about ELECTRONIC DESIGN. Here is a concentrated audience of 25,000 engineers ready to read about the advantages offered by your plant.

Remember, more than 5,500 ELECTRONIC DESIGN readers inquire every issue—many of them will be interested in your job opportunities.

You can efficiently reach them in ELECTRONIC DESIGN'S "Career's Section."

AEROJET-GENERAL CORPORATION
AVIONICS DIVISION
Offers Outstanding Opportunities For ELECTRONICS ENGINEERS and PHYSICISTS in the field of INFRARED DETECTION

*RESEARCH PHYSICISTS. To perform research and development on the basic design of infrared devices. Should have broad background of electronics, optics, and basic mechanical design. Understand and perform analysis of infrared equipment. M.S. or equivalent in physics or electrical engineering.

*ELECTRONICS ENGINEERS. B.S. EE or higher for design, development and manufacturer (pilot run quantities) of electronic, electro-mechanical and optical equipment. Experience in one of the following: electronic packaging; missile control and handling systems; circuit theory; instrumentation; system test; transistor application; printed circuitry; miniaturization.

*PROJECT ENGINEERS. Minimum 4 years experience. Administer and direct programs involving the evolution of electro-optical-mechanical design and development of infrared detection systems. Responsible for budgeting, scheduling and all technical aspects of these programs. Electrical Engineering degree.

*MECHANICAL DESIGN ENGINEERS. D.S.M.E. or M.S.M.E. to apply engineering fabrication knowledge to improve processes, techniques and tooling. Familiar with airborne instrumentation, computers or other miniaturized electro-mechanical equipments. Experience required in one of the following fields:

  ELECTRO-MECHANICAL: Fire control, servo design, or electronic packaging. INSTRUMENTATION: Accelerometers, aircraft control and automation devices. OPTICAL: Telescopes, interferometers, optical measuring and computing systems. COMPUTER: Digital and analog, airborne computer equipment.

*OPTICAL PHYSICISTS-ENGINEERS. For research and development on the design of special optical systems for use in infrared devices. Background in optical system design with special optical materials. Familiar with the techniques of optical system design, construction, alignment and testing.

You are cordially invited to send a detailed technical resume to:

MOTOROLA, INC.
During World War II, Eastern Industries pioneered cooling systems for aircraft electronic systems. Now, thousands of installations later, and as the leader in this challenging field, Eastern is still pioneering. Experience has been a springboard to new developments... compactness, simplification, refrigeration cycles. Research and development continue to play their vital parts in perfecting systems to overcome the new problems as expanded aircraft performance produces fantastic rises in temperatures.

If you have a challenging problem, come to the leader in the field for complete and creative engineering help.

**ELECTRONIC TUBE COOLING UNITS**

Custom-made units, with or without refrigeration cycles, provide a method of maintaining safe operating temperature limits in electronic equipment. Standard sub-assemblies and components normally are used to create a custom-made design to fit your exact needs. Costs are minimized for these completely self-contained units by combining heat exchangers, fans or blowers, liquid pumps, reservoirs, flow switch, thermostat, and other common components.

DIGITAL VOLTMETERS

DIGITAL OHMMETERS

DIGITAL RATIOMETERS

or a COMPLETE DIGITAL, MISSILE ELECTRICAL CHECKOUT SYSTEM
The development of the RCA-6AF4-A...outstanding for superior quality...is just one example of the effectiveness of RCA's continuing program to provide manufacturers with tubes of uniformly high quality at moderate cost.

Troublesome days--The "cage" structure originally used in the 6AF4 was the only one readily available that would satisfy the oscillator-service requirements of UHF television receivers. In spite of certain shortcomings of the 6AF4 structure, the tube has been popular with manufacturers needing a UHF-oscillator triode. To eliminate the shortcomings of the 6AF4, RCA undertook an extensive redesign of its structure.

Now, an outstanding tube--Today, the RCA-6AF4-A is considered by manufacturers to be outstanding in all respects. Critical evaluations show clearly that the improved RCA-6AF4-A offers such distinct advantages as minimized slump, product uniformity, and long life.

Dynamic life-tests prove RCA's quality--Projected average life for this tube type is 4,000 hours or more, based on life tests under dynamic conditions at 1,000 Mc. The new RCA-6AF4-A, a Preferred Tube Type, is certainly the right choice for manufacturers designing new UHF-TV tuners and receivers.

RCA's Preferred Tube Types Program currently offers a list of 62 tube types for TV and radio receiver applications. Tube types on this "list" have qualified as Preferred Tube Types by meeting these 4 important requirements: Quality...it performs adequately in each function for which it is chosen; Versatility...the tube's characteristics are suitable for a wide variety of applications; Popularity...it is among the popular currently used types; Economy...the tube is adaptable to low-cost manufacturing techniques.

You, too, can gain for your own designs and products, the benefits offered by RCA's Preferred Tube Types Program. Contact your RCA Field Representative for the up-to-date list of RCA Preferred Tube Types. Or, write RCA Commercial Engineering, Section D-18-Q-3, Harrison, N. J.
