Gold-plated pie-plate below is a telemetry transmitter for an artificial earth satellite. The transmitter uses a new phase modulator circuit described on p 68.
NEW RAYTHEON MAGNETRONS FOR A WIDE RANGE OF APPLICATIONS

Designed for C-band systems requiring tunability, the RK-7156 magnetron has a minimum peak power output rating of 250 kilowatts over a frequency range of 5,450 to 5,825 megacycles. Applications include a flight-tested, revolutionary airborne weather radar system. The RK-7156 is in quantity production.

CIRCLE 276
Reader Service Card

RK-7156

* * *

X-band magnetron for airborne search radar provides one megawatt minimum peak power and 875 watts average power within a frequency range of 9,340 to 9,440 Mc. Designated QK-624, this pulsed-type tube is liquid cooled and should give at least 1,000 hours of reliable service.

CIRCLE 277
Reader Service Card

RK-7529

* * *

For ground-based and airborne radar systems, the RK-7529 magnetron provides a 2.0 microsecond pulse of 3.5 megawatts minimum peak power over 2,700 to 2,850 Mc. This liquid-cooled tube is interchangeable with other fixed-frequency S-band tubes operating at similar power levels.

CIRCLE 279
Reader Service Card

RK-7578

* * *

Developed to withstand extreme environmental conditions, the RK-7449 magnetron is a lightweight, compact tube with a minimum peak power output of 45 kilowatts at the operating frequency of 24 Mc. The RK-7449 is required to withstand repeated shocks of 50G. Stable operation is guaranteed at vibration frequencies up to 2,000 c.p.s. with 30G applied.

CIRCLE 259
Reader Service Card

RK-7449

A one kilowatt beacon magnetron, the RK-7578 weighs only 14 ozs., yet will withstand vibrations of 15 G's at 20 to 2,000 cycles and shock up to 100 G's. It is mechanically tunable and covers the 5,400 to 5,900 Mc range.

Bandwidth of ten to one or greater independent of frequency—that's why system planners in communications, back scatter, range instrumentation, signal intercept and ECM are excited about log-periodic antennas. Translating this new theory into practical hardware is a specialty of Granger Associates; one of the few organizations that not only understands the concept, but actually builds log-periodics and delivers them to highly satisfied customers. Our accomplishments in this category include omnidirectional designs, high gain pencil beam designs, designs that permit remote selection of polarizations, feeds for reflectors, direction finders, scanning and switched beam arrays. System planners will also find G'A an excellent source for low noise preamplifiers, receiving multi-couplers, wide-band baluns, special purpose transmitters. They will find more: an adroit team of specialists with a unique approach to problem solving that results in dependable equipment—the right kind at the right time.

TIROS relies on LAMBDA reliability

Standard Lambda Regulated Power Supplies have again been selected for a job where reliability and quality are of vital importance. They power the ground equipment in the primary and back-up stations that control and track America’s newest missile—TIROS.

In TIROS as in SAGE, Digital Computer Intervention and Display System and other leading electronic projects, Lambda Power Supplies are specified because Lambda equipment has consistently proven its reliability.

This same Lambda quality is the reason Lambda Power Supplies are consistently selected first by engineers in independent surveys. To find out more about Lambda Supplies, which are guaranteed for a full five years, send today for the Lambda Catalog. It gives data on Lambda’s complete line of tube models ranging up to 525 VDC and transistor models up to 10 Amps.
TUNNEL DIODES AND RADIATION. Today radiation is becoming increasingly important as a factor to be reckoned with in the design of electronic instruments for space research probes and satellites. This is certain to become even more apparent as work begins on the SNAP-8 nuclear electric power regenerating system for spacecraft.

With future needs in mind, ELECTRONICS editors have been studying available knowledge of what effect neutron bombardment has on electronic devices. Since the tunnel diode has been so much in the news, Assistant Editor Wolff questioned several research labs about it. What he learned, which may surprise some, is on p 32.

SELF-HELP PAYS OFF. Banding together to let industry know the potential of an area... and to go after business... can pay off in results. A case in point is Long Island, where morale and business volume had shown signs of lagging behind other parts of the country. Executives of many small L.I. firms have joined forces to paddle their collective canoe. Already the results are promising. One survey taken among 35 companies shows that combined net sales for the group went from $387,725,000 in 1954 to more than $600 million by 1959. They expect to pass the $633-million mark by the end of this year. Associate Editor Emma made a series of plant tours and conducted interviews. For details of what he found, see p 28.

COMING IN OUR MAY 13 ISSUE

MICROSOLIDS. Work with semiconductors, thin films, passive and other materials in combination is presently at a stage where a diversity of opinion exists as to what the prime objective should be. Some researchers believe a major improvement in reliability is of greatest importance. Others think that a significant reduction in size and weight should be the prime objective. Still others feel that cost reduction should be paramount.

Next week ELECTRONICS adds to the growing list of feature articles which have kept our readers out front concerning various approaches to future circuitry. Three members of the Semiconductor-Components Division of Texas Instruments Incorporated team up to state their concepts. J. W. Lathrop, R. E. Lee and C. H. Phipps discuss reliability, size and weight, and cost.

Their article also describes in detail a fabrication technique which combines oxide masking diffusion, metal deposition, alloying and surface shaping. You’ll learn how a complex circuit is developed, from schematic diagram to network, on and within a single-crystal semiconductor wafer.

Lathrop is a senior project engineer working on semiconductor networks and is well known for his work at Diamond Ordnance Fuze Laboratories on ceramic-base printed circuits. He holds a Ph.D in Physics from MIT. Lee is manager of the Semiconductor Networks department, heading a project team responsible for design, development, engineering, production and marketing of such networks. He is also head of the Circuit Development branch of the Semiconductor-Components Division, has worked on radar anti-jamming, aircraft fire control systems and guided missile range instrumentation. He holds a Ph.D in Electrical Engineering from Stanford University. Phipps is marketing manager of the Semiconductor Networks department. He holds a B.S. in electrical engineering from Case Institute of Technology and an M.B.A. from Harvard.

COMMENT

Tracking Telemetry Antenna

With reference to the article "Tracking Radar for Tiros Weather Satellite" (p 57, Apr. 15), I wish to correct the title. The title as published was not that which was submitted on the original manuscript. Indeed, the system described in the article is not a radar but is rightfully classified as a telemetry and space communications receiving system.

Since the time that the original manuscript was submitted, Radiation Incorporated engineers have added to the design so that automatic tracking on the 108 mc band is included. The conical scan error signal at 10 cps is generated by prism rotation. The 108 mc signal is preamplified, converted to the 216-260 mc band, and carried to the telemetry receivers through the existing RF plumbing.

H. E. O'Kelley
Melbourne, Fla.

Thank you for your letter of Apr. 15. Of course you are quite right—the title we used for your article was a case of over-exercised editorial license.

Wire Mesh Cushions

In your article, "Resilient Mesh Cushions System" (p 94, Mar. 18), the reference of knitted wire to pot cleaners could well be misinterpreted by those engineers who are not familiar with the engineering which has gone into the development of MET-L-FLEX cushions.

The MET-L-FLEX resilient cushions used by Robinson Technical Products in systems consist of a high grade of stainless steel round wire held to close diameter tolerances and fabricated by a knitted process and carefully rolled, and cramped and compressed to exacting requirements.

Pot cleaners are heterogeneous mixtures of loose fibers without regard to any continuity and with no attempt for homogeneous density. Furthermore, wires used in pot cleaners are flattened with sharp edges which are necessary for the scrubbing action required. The use
A guide for predicting resistor performance

NOMOGRAPHS PREDICT LIFE PERFORMANCE OVER LONG PERIODS OF TIME FOR ALLEN-BRADLEY HOT MOLDED COMPOSITION UNITS

Allen-Bradley's exclusive hot molding process produces resistors with such uniform characteristics that their performance can be predicted with a high degree of certainty. Test data produced in the last 20 years not only in the Allen-Bradley environmental laboratories but also in independent laboratories have been carefully compared and analyzed and have served as a basis for developing the above power nomographs.

And Allen-Bradley has been conservative in projecting test data. Inasmuch as catastrophic failure has yet to occur, the design engineer can develop circuitry with predictable performance.

WRITE TODAY—Power nomographs for standard Allen-Bradley composition resistors are published in Technical Bulletin 5000E. You'll find this information of genuine help and value to you.
Here is a recently developed plier specially designed for electronic use. It will fit into confined space and the steel jaws hold clipped end of sheared wire firmly... nothing to wear out.

The shear blade is at an angle of 15 degrees (the standard angle of regular diagonal pliers). Shear principle assures smooth, continuous action without snap, preventing shock which might damage transistors and other delicate components. For use with bare wire up to 18 gauge.

See your electronic supply house or write for catalog.
OHMITE

RHEOSTATS

NOW 11 Sizes! 12½ to 1000 Watts

Ohmite offers you industry's most complete line of rheostats. All sizes are available from stock in a wide range of resistance values, including the NEW Model "E." Ten sizes are available to meet MIL-R-22A requirements in each of the 26 type designations.

16 Quality Engineering Features:

1. Vitreous enamel bonds the core and base together into one integral unit.

2. The wire is wound over a solid porcelain core, and each turn is locked against shifting by vitreous enamel. Uniform or tapered winding.

3. Close graduation of control. Each turn of wire is a separate resistance step.

4. Large, flat surface upon which the contact brush rides.

5. Metal-graphite contact brush (varied to fit current and resistance) insures good contact, with negligible wear on the resistance wire.

6. Shunt pigtail of ample size carries the current directly to the slip-ring.

7. Large slip-ring of high-current carrying ability minimizes mechanical wear and provides connection from the moving contact to the terminal.

8. Potentiometer use. The rheostats are provided with three terminals so they can be used as potentiometers or voltage dividers.

9. High strength ceramic hub insulates the shaft and bushings from all live parts. All sizes will stand a 3000 volt a-c breakdown test to ground.

10. The contact arm is a long tempered steel spring which assures uniform contact pressure at all times. Cadmium-plated for corrosion resistance.

11. Rounded pivot holds contact brush in flush-floating contact with wire.

12. Stops which are keyed to the shaft and base limit the rotation—thus no torsional strain is imposed on the contact arm on stopping.

13. Compression spring maintains uniform pressure and electrical contact between slip-ring and center lead at all times.

15. Ohmite rheostats meet requirements of NEMA and EIA (formerly RETMA).

16. There are only ceramic and metal in the construction of Ohmite rheostats—there is nothing to char, burn, shrink, or deteriorate.

Write on company letterhead for Catalog 58.

electronics • MAY 6, 1960
Atmospheric turbulence has the characteristic of reflecting microwave signals, with the degree of reflection depending on the severity of the turbulence. Returned to the aircraft, this reflected radar warning is displayed in a manner that warns the pilot of the exact location and extent of the turbulence, enabling him to change his course and fly around dangerous storms. Since the radar display also shows him "holes" in storms where there is little or no turbulence, the pilot can choose a course that will result in maximum safety and minimum delay.

Commercial airlines use Varian klystron-equipped weather radar to assure the comfort and safety of passengers and to reduce the minimum of storm hazards and delays. Photo above shows radar antenna inside the Radome nose of a United Air Lines plane.

In addition to the technical advantages of Varian klystrons to the equipment designer, their rugged mechanical construction and long life are vital benefits to the user. These characteristics are reasons why Varian has become the world's largest manufacturer of klystrons.

ELECTRONICS NEWSLETTER

STRETCH Computer Handles 100 Billion Computations A Day

Announcement of the solid-state, $10-million-and-up STRETCH class of computers highlighted last week's annual meeting of shareholders of International Business Machines Corp. in New York.

The new class of computers, the same size as the IBM 704 but 75 times faster, can complete 100 billion computations in a day. They will be similar to the STRETCH computer being completed for the Atomic Energy Commission at Los Alamos, N. M.

Typical system has internal capacity of more than 11 million decimal digits, with retrieval rate of 2.18 millionths of a second from the main units. Company says that since several storage units can be operated at once, the system will accommodate 2 million instructions and 2 million pieces of data a second.

An "exchange" computer within the system routes information over 32 channels, each of which can handle many input-output devices that are compatible with existing IBM computers. Some STRETCH computers will have a new random access magnetic disk storage. A "Look-Ahead" device enables the computer to anticipate what is to come and automatically assign tasks to its various parts.

IBM president Thomas J. Watson, Jr. said the small unit costs of work performed at STRETCH speeds make the machine ideal for IBM Tele-processing data systems.

Announced last month, these systems can gather information from many points, process and store it in a central computer, and make the data available to all points on demand.

At the other end of the speed and cost range from STRETCH, IBM announced the new solid-state, general-purpose 609 punched card calculator which will rent for $1,175 a month or sell for $55,500. Company says it performs additions and subtractions at microsecond speeds (12-digit numbers in 392 microseconds), and multiplications and divisions in milliseconds. Also disclosed: New TRACTOR magnetic tape system that can store 60 billion characters and will read and write at a speed of 11 million letters or numbers per second.

B-58's Countermeasures System Cost $124 Million Over 6 Years

Delivery of the first operational Convair-made B-58 Hustler to the Strategic Air Command prompted release of information last week about work on the plane's "invisible electronic shield." Sylvania said it has been awarded more than $124 million in contracts over the last six years for development and production of the system, which batters radar and radar-guided missiles.

The electronic system has been fully integrated to meet the specific space and weight needs of the B-58, as well as its electrical, electronic and thermal characteristics, it was disclosed. The lightweight countermeasure system consists of three major subsystems: radar warning, chaff dispenser control and radar track breaker.

Studying Use of SAGE In Air Traffic Control System

Two study programs relating to the possible use of the SAGE continental air defense system for air traffic control are now underway.

One involves a two-year $5,974,500 contract awarded by the Federal Aviation Agency to the MITRE Corp., Lexington, Mass. The contract covers design of and experiments with a semiautomatic air traffic enroute control system using current air defense SAGE facilities. Cost will be shared by FAA and USAF.

FAA says the project will use a SAGE computer at Lexington and long-range radars in New England, New York and New Jersey. The agency says the test facility will tie in with experimental gear at the National Aviation Facilities Experimental Center near Atlantic City, N. J. (ELECTRONICS, p 28, Apr. 8).

Second program is FAST (for Flight Advisory Service Test), part of a larger joint Air Force-FAA project (TRAILSMOKE) which will run through the summer. FAST marks the first operational evaluation of the SAGE Direction Centers by FAA traffic controllers, uses selected controllers at 38 sites in a test of the system's capability to provide civil and military planes with radar advisory information on potential air traffic conflicts.

NEWS BRIEFS . . .

G. Barron Mallory has been elected president of P. R. Mallory & Co., Indianapolis, Ind., succeeding Joseph E. Cain. Philip R. Mallory was re-elected chairman of the board of directors. Cain was elected senior vice president of the board and chairman of the executive committee.

Charles Barnes was elected vice president for finance and Leon Linn was elected vice president.

Ballistic missile computer for the Sky Bolt GAM-87-A guidance system will be supplied by GE's Light Military Electronics department. Northrop's Nortronics division has guidance subsystem responsibility for the air-launched missile. Douglas Aircraft Co. has USAF prime weapons systems contract.

Electron tube sealing process using optically-ground and mated glass stems and envelopes is expected to extend life of military tubes. Method, called polyoptic sealing, enables evacuation of tubes before sealing, preventing degradation of internal elements. Chatham Electronics division of Tung-Sol Electric Inc., developed production methods under a contract with U. S. Army Signal Supply Agency. In a sample lot of miniature hydrogen thyatrons produced by the method, 75 percent were still operating after 1,500 hours. Flame-sealed tubes of the same type showed a 90-percent failure rate after 1,500 hours.

NASA has selected Aeronutronic division of Ford Motor Co. for negotiations leading to construction of a 300-lb instrumented package to be landed on the moon in 2 years.
Here is Francis Alterman, Manager of General Mills Digital Computer Laboratory, checking one of our newest computers which he helped design. General Mills computers, both analog and digital, are being used in missile guidance, bombing and navigation systems, automatic surveying and in industrial control. In future space travel, computers will help control navigational systems of space vehicles and will process data gathered in outer space.

General Mills engineers work today.

General Mills has been producing computers for nearly 20 years. Exciting new concepts in high speed magnetic tape units, ultra-high precision analog to digital converters and optical keyboards are examples of continuous developments in our over-all computer program. We work to improve reliability, increase speed, cut cost.

Our research activities cover broad areas in physics, chemistry, mechanics, electronics and mathematics. Some of the studies representative of these activities are: ions in vacuum, deuterium sputtering, dust erosion, magnetic materials, stress measurements, surface friction and phenomena, trajectory data and infrared surveillance.

In our engineering department, current projects include: specialized inflatable vehicles and structures, airborne early warning systems, micro wave radar test equipment,
Mars seen from one of its moons . . . illustration from book written for General Mills by Willy Ley.

to help you explore space tomorrow

antennas and pedestals, infrared and optics, inertial guidance and navigation, digital computers—and many other activities.

Our entire manufacturing department is geared to produce systems, sub-systems and assemblies to the most stringent military requirements. Our people have a wealth of experience in complex military projects.

To wider worlds—through Intensive Research • Creative Engineering • Precision Manufacturing

CIRCLE 13 ON READER SERVICE CARD
THE DEFENSE DEPT. has stirred up a new rumpus with a proposal to control "controversial" or "inappropriate" advertising and public relations activity by military contractors.

The new rules would go far beyond current security restrictions. They are in line with the Hebert Committee's recommendations that the Pentagon clamp down on advertising and PR which "provokes controversy and promotes dissension, and introduces biased, narrow, and prejudicial considerations into purely military decisions".

This is what the new Pentagon regulation would bar: "inappropriate claims" of operational availability or capability of new weapons; discussion of the economic impact of contract awards or cutbacks; discussion of relative merits of conflicting military strategy which might affect contracting.

THE PENTAGON'S new $700-million budget overhaul includes the special allocation of $16.7 million to offset "price adjustments" and production delays in procurement of Air Force surveillance radar.

Of this sum, $1.3 million is earmarked for use in the next three months, the remainder for fiscal 1961 starting July 1. The Air Force won't identify the contractors involved. The equipment includes height-finder radars and low-powered gap filler radar. The $16.7 million is being added to a $225.9-million radar procurement budget for fiscal years 1960 and 1961.

ELECTRONIC INDUSTRIES ASSOCIATION has objected to the Labor Dept.'s proposed definition of the "electronic equipment" industry for purposes of a survey of prevailing wages. This would be the first step in the prolonged determination of a Walsh-Healey minimum wage for producers of end-items.

Walsh-Healey determinations are now also under way for producers of electron tubes and semiconductors and of component parts. The end-item case is in the earliest phase of the three electronic Walsh-Healey cases.

The Labor Dept.'s proposed industry definition covers "the manufacture of electrical apparatus and sub-assemblies . . . involving the use of electronic tubes and/or solid state semiconductor devices."

EIA claims this definition would conflict with Walsh-Healey definitions of other electronics industry segments. Instead, the association proposes a definition in terms of classes of products the industry makes—and limited to those that are specifically electronic.

Examples: radio and TV transmitters and receivers; electronic navigational devices; electronic sound distribution devices; electronic search, detection, surveillance, and tracking devices; etc.

THE PENTAGON has made a special analysis of prime contract awards to the 25 leading contractors in fiscal 1959. It shows that 40.9 percent of the contracts (in terms of dollar value) were awarded on a fixed-price basis and 58.6 percent on a cost-reimbursement type basis.

The 25 leading contractors accounted for $12.3 billion worth of military business—or 54.6 percent of the total value of defense contracts placed in fiscal 1959.

Over half the fixed-price contracts included incentive provisions—that is, the contractor's profit allowance increased or dropped as production costs fell below or exceeded contract target prices. The next most common type of fixed-price contract provided for a firm fixed price.

All but $800 million worth of the cost-reimbursement type contracts included fixed fees—that is, the contractor was awarded a specific percentage of the costs as his profit. Only one percent of the contract awards to the 25 top companies were made on a formally advertised basis.
Doing pulsed or "fast" circuit work?

Square Wave Generator
1 cps to 1 MC; 0.02 µsec rise time

**hp 211A Square Wave Generator.** Versatile, wide range instrument for testing oscilloscopes, networks, video and audio amplifier performance, modulating signal generators, measuring time constants. Offers simple control of electronic switchers; is also convenient for indicating phase shift, frequency response and transient effects.

Special features include two separate outputs — a 7 volt, 75 ohm circuit for television work and a 55 volt, 600 ohm output for high level work. Both outputs offer full amplitude variation. May be operated free-running or externally synchronized with positive-going pulse or sine wave signal of 5 volts minimum amplitude. Compact, weighs only 25 lbs. Cabinet model, $300.00; rack mount model, $305.00.

Pulse Generator
0.07 to 10 µsec pulses, 0.02 µsec rise time

**hp 212A Pulse Generator.** Time saving basic instrument for radar, television and other "fast" circuit work, including testing rf amplifiers, filters, band pass circuits; oscilloscopes and peak measuring equipment, pulse modulating uhf signal generators. Offers positive or negative pulses of 50 watts amplitude, delay and advance sync out circuits for synchronizing to other circuits, direct-reading pulse length control, high quality pulses with 0.02 rise and decay, flat top and minimum overshoot. Jitter less than 0.01 µsec. Permits delivery of accurate pulses to end of long transmission lines; if line is correctly terminated, pulse shape is independent of line length, sync conditions, input voltage or output attenuator setting. Internal impedance 50 ohms or less, either polarity. Repetition rate, internal sync 50 to 5,000 pps, external sync approximately 2 to 5,000 pps. Cabinet model $585.00; rack mount model, $570.00.

Call your hp representative for details or write direct.

Open your eyes to new amplifier designs!

See how to combine tape wound cores and transistors for more versatile, lower-cost, smaller amplifiers.

Tie tape wound cores and transistors into a magnetic-transistor amplifier, and open your eyes to new design opportunities.

To start with, these are static control elements—no moving parts, nothing to wear or burn out. Next thing you find is that you reduce components' size—your amplifier is smaller and costs less. That's because between them the core and the transistor perform just about every circuit function...and then some.

For instance? The core has multiple isolated windings. Thus you can feed many inputs to control the amplifier. The core also has a square hysteresis loop, and thus acts as a low loss transformer. That means you save power. In addition, the core can store and remember signals—so time delay becomes simple.

There's no need for temperature stabilization, either. The transistor acts only as a low loss, fast, static switch—and in this function it has no peer.

How do you want to use this superb combination? As a switching amplifier—or a linear one? In an oscillator? A power converter (d-c to d-c or d-c to a-c)? You'll have ideas of your own—and if they involve tape wound cores, why not write us? Ours are Performance-Guaranteed. Magnetics Inc., Dept. E-81, Butler, Pennsylvania.
LOW POWER. Consider the high-efficiency Raytheon 1N536 series.

MEDIUM POWER. Look into the Raytheon 1N253 and the new 1N2512 series.

Raytheon diffused junction (upper photo) gives utmost uniformity, highest performance, greatest reliability. Compare with irregular fusion junction (below).

HIGH POWER. Note the all-new Raytheon 1N248A, 1N1191A and 1N1195 series.

For reliable power . . .

Depend on diffused junction rectifiers!

Here are reliable Raytheon diffused junction silicon rectifiers spanning the complete semiconductor power spectrum.

Raytheon manufacturing success in diffused junction rectifiers has long provided fast recovery, low forward voltage drop and extreme uniformity of device characteristics. Outstanding mechanical design and production under stringent quality control result in rectifiers with excellent ratings and characteristics. Utmost reliability is assured by constant life and environmental testing beyond the most stringent requirements of Mil 19500B, over the guaranteed temperature range of -65°C to +165°C.

Of special interest in low current applications of the 1N536 series are the excellent reverse recovery, fast start and fast rise of Raytheon diffused junction rectifiers.

In the four amp range, the Raytheon 1N2512 series features low reverse current and is available in three package styles: with insulated stud, stud connected to anode, or stud connected to cathode.

In the higher current range, the new Raytheon diffused junction silicon rectifiers offer ratings up to 22 amps (at 150°C) — plus the important advantages of low forward voltage drop and high efficiency, for exceptional regulation in power applications.

Further information on all these reliable Raytheon rectifiers is given on the following page. Semiconductor Division, Raytheon Company, 215 First Avenue, Needham Heights 94, Massachusetts.

RAYTHEON SEMICONDUCTORS
Raytheon diffused junction silicon rectifiers

LOW CURRENT SERIES. The fast reverse recovery, low current Raytheon rectifiers. Feature both fast start and fast rise. Temperature range —65°C to +165°C.

The world-famous

AEROCOM 1046
TRANSMITTER

1000 W CARRIER POWER
WITH HIGH STABILITY

telegraph A1, telephone A3 and FSK (Radio Teletype). It can be remotely controlled using one pair of telephone lines plus ground return with Aerocom Remote Control Equipment. Front panel switches and microphone are included for local control.

Four crystal-controlled frequencies (plus 2 closely-spaced frequencies) in the 2.0 - 24.0 megacycle range can be used one at a time, with channeling time only two seconds. Operates into either balanced or unbalanced loads. The power supply required is nominal 230 volts, 50 - 60 cycles, single phase.

The housing is a fully enclosed rack cabinet of welded steel, force-ventilated through electrostatic filter on rear door.

Telegraph keying (A1): Up to 100 words per minute. Model 1000 M Modulator (mounts in transmitter cabinet) is used for telephone transmission; a compression circuit permits the use of high average modulation without over-modulation. Model 400 4 Channel exciter is used for FSK.

Output connections consist of 4 insulated terminals (for Marconi antenna) and 4 coaxial fittings Type SO-239, which can be used separately or in parallel in any combination. For 600 ohm balanced load, Model TLM matching network is used, one for each transmitter channel.

As in all Aerocom products, the quality and workmanship of Model 1046 are of the highest. All components are conservatively rated. Replacement parts are always available for all Aerocom equipment.

Complete technical data on Aerocom Model 1046 available on request.

HIGH CAPACITY STATIC INVERTERS WITH NO MOVING PARTS

Delco Radio's high capacity Static Inverters and Converters fill a critical need in missile guidance and control—offering extremely reliable, very highly regulated power of precise frequency. The Static Inverters use direct crystal-frequency control and digital logic circuits to produce accurate, single or polyphase power output. They have no moving parts. There is nothing that can get out of adjustment. Electrical characteristics are: High Capacity—150 to 4,000 volt-amperes. High Efficiency—65 to 90% depending on power and control (precision and regulation) required. Accurate Phase Angle Control—to 0.5 degree. Precise Frequency Control—up to 6 parts per million maximum variation under all load and environmental conditions. Voltage Amplitude Control—to ±1% no load to full load. Low Distortion—typically 2% total harmonic distortion. Delco Radio has developed and produced power supplies for missiles such as the Air Force's Ballistic Intermediate Range Thor, Intercontinental Titan, and the pilotless aircraft Mace. For further information on military electronics, write to our Sales Department. Physicists and electronics engineers: Join Delco Radio's search for new and better products through Solid State Physics.

100:1 miniaturization with Solid Circuit semiconductor networks

Now — 3 years ahead of industry's expectations — Solid Circuit semiconductor networks from Texas Instruments for many of your high-reliability miniaturized systems!

Solid Circuit networks are a major departure from conventional components because they integrate resistor, capacitor, diode, and transistor functions into a single high-purity semiconductor wafer. Protection and packaging of discrete elements is eliminated, and contacts between dissimilar materials are minimized, reducing element interconnections as much as 80%. Fabrication steps have been reduced to one-tenth those required for the same circuit function using conventional components.

Only a few process steps and time-proved TI mesa production techniques permit a high degree of process control in Solid Circuit network fabrication. The result of these facts: reliability is built into each Solid Circuit network.

If you need to reduce equipment size and weight—or to design a more complex system in the same size—investigate Solid Circuit networks for your missile, satellite, space vehicle, and other microelectronic programs. TI engineers are ready to custom design this concept to your requirements. Contact your nearest TI Sales Engineer today. The TI Type 502 Solid Circuit network is immediately available for your evaluation.

An assembly of 13 Solid Circuit networks, actual size, performs a full serial adder function, replacing 85 conventional components with a 100:1 size reduction. Weight: 1.5 gm. Volume: 0.02 cubic inch.

*Trademark of TEXAS INSTRUMENTS INCORPORATED

TI Type 502 silicon Solid Circuit network is intended for binary counter, flip-flop, or shift register applications. The dimensions of the glass-to-metal hermetic-sealed package are 0.250 x 0.120 x 0.030 inch.

TAPCO ANALOG COMPONENTS

For airborne equipment

TAPCO analog components have been proved in various classified aircraft and missile applications. The TAPCO line includes:

- Position Servos
- Velocity Servos
- Miniaturized Servo Amplifiers
- Tracking Computers
- Data Conversion Units
- Arithmetic Computers

PERFORMANCE DATA: TRANSISTORIZED EIGHT-SPEED SERVO (Illustrated at left)—Speed Range: From 1 to 2.5 rpm. Speed Tolerance: ±0.2% over temperature range of 50°F to 85°F. Angular Vibration Tolerance: 5 x 10^-5 radians double amplitude. Acceleration: Zero to maximum speed within 0.2 seconds. Transition time: Speed change time within 0.1 seconds. Torque Output: 100 oz. in. with 15 watts input. Higher torque available with increased power consumption. Power Requirements: 10.0 watts steady rate. 18 watts peak during acceleration or speed change. PHYSICAL DATA—Size: 10 3/4" x 7 3/4" x 8 1/2". Weight: 5 3/4 lbs.

For ground support equipment

All TAPCO GSE analog computer components use MIL-approved parts for highest reliability. Modular construction of these components allows compact assembly on chassis. The TAPCO line includes: DC Operational Amplifiers, Servo Amplifiers, Buffer Amplifiers, Electronic Modulators, Position and Rate Servos, Vector Servos, Aircraft Dynamic Simulator, Coordinate Converters, Special Multipliers and Dividers, Ballistic Computer.

For further information, write on your company letterhead indicating your specific product interest.

FINANCIAL ROUNDUP

GE Orders Rise 9 Percent

First-quarter sales for General Electric Co. this year totalled $957,-
435,000, off two percent from the equivalent period of 1959 when the
figure was $976,588,000. Net earn-
ings for both periods were "practi-
cally identical," according to GE,
with this year's amount standing
at $52,614,000 or 60 cents a share.
R. J. Cordiner, company chairman,
calls the outlook for the remainder
of the year "favorable" and says
total orders received for all GE
products are up 9 percent over last
year's first quarter. The net earn-
ings of $52.6 million were equiva-
 lent to 5.5 cents per dollar of sales,
a slight rise over the 5.4 cents for
a year before.

The Martin Company reports in-
creases in sales and earnings for
the first quarter of this year. Sales
and other income came to $140,-
899,907, compared with $122,332,-
650 in 1959, an increase of 14.9
percent. Net income after federal
taxes rose 14.8 percent in 1960 to
$3,488,112, up from $3,038,470. Net
income in 1959 was $390,397, equal to
5.5 cents per dollar of sales,
so important for military acceptance.

Whether it's for reliability and life testing,
design or system analysis, utilization studies
... or to continuously monitor and log
critical equipment or components... when
you incorporate the Waltham WT-1 in your
plans, you add that "measure of reliability"
so important for military acceptance.

The above figures represent sales of electronics
stocks on the New York and American Stock
Exchanges. Listings are prepared exclusively for
ELECTRONICS by Ica Haupt & Co., investment
bankers.

CIRCLE 23 ON READER SERVICE CARD 23
NOW AVAILABLE
Rugged New Eimac X778
Traveling Wave Tube ...
One Watt Output, 55-60 db Gain

Purchase orders are now being accepted on Eimac's pioneering new high gain traveling wave tube, the X778.

Unique features of this advanced one watt CW traveling wave tube include its exceptionally wide frequency range—5.0 to 11.0 KMc., small signal power gain of 55-60 db, and light weight permanent magnet focusing.

Like all other Eimac ceramic-metal tubes, this TWT "can take it."

The X778 was especially designed to operate under severe environmental conditions of shock, vibration, temperature variation and high altitude. Breakage is a thing of the past, resulting in greatly reduced tube replacement costs.

The Eimac X778 finds wide usage in electronic counter-measures, radar augmentors, data links—in any application where more than one tube would normally be required to cover the C and X bands. This means significant cost reduction and increased system reliability.

Contact R & D Marketing Department for additional details and information on how this tube type may be modified for your requirements.
USN·USAF·SAC standards are met by SYLVANIA TRANSISTORS

SYLVANIA-1655 . . . for example, is used extensively in POLARIS. Imagine the complexity of the electronic system that must obtain target data, translate it into launching information and transmit intelligence to the guidance system of the "bird." Here, there can be no compromise with reliability. That's exactly why SYLVANIA has become a principal source of supply for NAVY-type R-212 (SYLVANIA-type SYL-1655) PNP-transistors used in the Polaris "bird" and its underwater "nest."

SYLVANIA-2N388 meets all requirements of MIL-T-19500/65 (NAVY). Originated by SYLVANIA, this NPN unit is designed and controlled specifically for computer applications where reliability, high gain and rapid switching capabilities are needed.

SYLVANIA-2N404 meets all requirements of MIL-T-19500/20 (USAF). This Sylvania PNP-type incorporates many of the features of the ultra-reliable SYL-1655 used in Polaris.

SYLVANIA-1729 is an NPN switching-transistor developed especially for SAC PROJECT 465L, the world-wide digital communications system. SYL-1729 is further proof of SYLVANIA capability in the design, production—and delivery—of reliable semiconductors.

Sylvania is prepared to custom-design semiconductor devices to your specific requirements, too. Contact your Sylvania Representative. For technical data on current types, write Semiconductor Division, Sylvania Electric Products, Inc., Dept. 224A, Woburn, Mass.
MARKET RESEARCH

Exports $415 Million, Down 3%

ELECTRONICS INDUSTRY exports in 1959 totaled nearly $415 million, less than 3 percent below record year 1958 exports of $427.7 million, according to a tabulation of month-by-month figures issued by the Foreign Trade Division of the Bureau of the Census.

The following table shows comparable dollar export figures in 1958 and 1959 for 21 product groups:

The Sixties will see marketing research and planning activities merging, Dr. Wendell R. Smith, RCA's director of marketing research and development, told the Electronic Industries Association's semiconductor marketing forum.

Pointing to use of techniques developed by market researchers in solving nonmarketing business problems, he sees the possibility that in some firms marketing research may become known as management research.

Big gains show up in test and measuring equipment (up 35.5 percent) in computers and associated equipment (up 29.8 percent) and in transmitters and equipment for radio and TV broadcasting (up 44 percent). Value of nuclear devices exported in 1959 is 50 percent higher than in 1958.

While consumer electronics has lost ground in 1959—radio and TV sets are down; so are phonographs, but not so sharply—most components are up. Semiconductors, capacitors and resistors all show healthy gains, although inductors, loud speakers and some tubes are down.

Biggest drop was in exports of land, sea and air mobile radio equipment, down 26.5 percent from $123 million in 1958 to $90.7 million in 1959.

The Sixties will see marketing research and planning activities merging, Dr. Wendell R. Smith, RCA’s director of marketing research and development, told the Electronic Industries Association’s semiconductor marketing forum.

Extending existing modulation systems to make more space available in the spectrum, and possibly even broadening the useful spectrum . . . this is a fundamental problem in modern communications. It is the problem to which ITT Laboratories is devoting intensive effort.

At the low end we're designing a new type antenna for very low frequencies. With a conventional antenna this would require a tower more than three miles tall. On the top side — at the high end — we're making radiation pattern surveys for the super high frequency bands. Here the entire antenna consists of a few millimeters of number eighteen copper wire. We're matching these efforts with advances in componentry . . . for instance, the parametric amplifier and now the ingenious ferroelectric converter which converts solar heat to high voltage electricity to power new satellite communications.

If you are a communications engineer who would like to be associated with some of the most significant programs in modern communications development . . . if you would like to work with men who are stretching the spectrum toward direct current at the bottom and the cosmic rays at the top . . . write Manager Professional Staff Relations . . . tell him your interests, your background and the kind of work you would like.

6.5" x 4" x 3.25" RF Amplifier
2 watts in — 100 watts out

800C — Sub-Carrier Oscillator
1.5" x 1.9" x 2.45"
Dev. Stab: ± 1% band width
Dev. Linearity: Less than 1% band width

Full Specifications & Details Available on Request
Only the New AIL Type 74 offers a continuously Tunable (40 to 180 mc) IF Amplifier for continuous automatic noise figure measurement

Adding new versatility to your Automatic Noise Figure Measurement equipment, AIL now offers the outstanding Type 74 Automatic Noise Figure Indicator with a tunable Frequency IF Amplifier... or you can purchase the Tunable IF Amplifier for modification of your present Type 74 equipment.

Single frequency units are also available with greater sensitivity and broader bandwidth.

The AIL Type 74 is designed to permit the adjustment of receiver parameters to minimize noise figure. No special training is required for use on the production line, in the laboratory, or in the field.

check these high performance features

Noise Figure Range, RF or IF.. High range — 23 to 36 db with extension to infinity
Low range — 0 to 25 db

Accuracy .................. Automatic: Low range ±1/2 db;
High range ±1 db
Manual: ±0.1 db with AIL
Type 30 Attenuator

Automatic Operation .......... AGC range: 65 db minimum
Manual Operation ............... Front panel IF gain control
Input Frequency ............... 30 and 40 to 180 mc (tunable); other frequencies available

Sensitivity ..................... 100 microvolts
Bandwidth ...................... 2.0 mc minimum
Recorder Outputs ................ Noise figure and AGC

Standard Models Available

A DIVISION OF CUTLER-HAMMER INC.
new high-power harmonic ABSORPTION filter for SL band—1700 to 2400 mc

Harmful harmonic interference from high-power microwave equipment should be, and can be, eliminated at the source. These unwanted signals literally disappear when passed through Sierra's new Model 204A Waveguide Filter.

Representing a new approach to the elimination of harmonic interference, the Model 204A actually absorbs the unwanted energy with no appreciable attenuation of fundamental signals within the pass band. High order harmonic, as well as low order, are equally attenuated.

Currently available for SL band frequencies, Model 204 type filters can be supplied for other frequency ranges on special order. See your Sierra representative or write direct.

SPECIFICATIONS

Pass Band: 1700 to 2400 MC
Insertion Loss: Less than 0.1 db in pass band
VSWR: Less than 1.1 in pass band, less than 1.3 above pass band
Attenuation: 40 db minimum, 3400 MC to 11000 MC
Same as RG-104/U below pass band
Maximum RF Power: 25 KW average, 1 megawatt peak
Size: 45" long, 12¾" wide, 10¾" high; weight 120 pounds.
Connections: UG 435A/U Flange
Price: Model 204A (SL Band) $2,195.00

Data subject to change without notice

NEW 10 KW AND 1 KW KLYSTRON POWER AMPLIFIERS

Two klystron power amplifiers, Model 216A (10 KW output) and Model 217A (1 KW) are now available from Sierra. Both units employ 4-cavity klystron tubes, and are designed for scatter communications systems, space programs and high power point-to-point data transmission systems.

Both units are continuously tunable from 1700 to 2400 MC and as broadband amplifiers provide a minimum gain exceeding 40 db.

Except for its heat exchanger, Model 216A (10 KW, pictured) is housed in three connected cabinets. Its frequency bandwidth is 18 MC at ½ power points. Model 217A (1 KW), is housed in one cabinet. Its ½-power bandwidth is 15 MC. Write for details.
How Radiation Affects Tunnel

Researchers at three companies now report severe degradation of tunnel diode's characteristics by exposure to certain magnitudes of nuclear radiation.

Evidence is mounting this week that Esaki tunnel diode characteristics are severely degraded by exposures to nuclear radiation of the order of $10^8$ fast neutrons/cm².

General Electric and Bell Telephone Laboratories' researchers now support results of work performed by Thomas A. Longo of the Sylvania Semiconductor division. Longo, who experimented with Sylvania tunnel diodes, reported his findings at a recent meeting of the American Physical Society.

Valley Current Increases

Longo's irradiation experiments with pile neutrons and 7-Mev electrons indicate that germanium tunnel diode characteristics are severely degraded with exposures of the order of $10^7$ neutrons/cm² and $10^8$ electrons/cm².

Principal effect is an increase of the valley current which washes out the negative resistance region. In Air Force-sponsored work, J. W. Easley and R. R. Blair of BTL noted similar results in germanium and silicon tunnel diodes which they tentatively interpret in terms of a bombardment-induced increase in the so-called diode excess current with little change of the band-to-band tunnel component of the total current.

For germanium tunnel diodes, an increase in valley current occurred at the rate of 10 percent per $10^7$ neutrons/cm² and the negative resistance, which was initially 9 ohms, increased on the order of 5 percent per $10^8$ neutrons/cm². From Fig. 1 it can be seen that at an exposure of $9.5 \times 10^8$ fast neutrons/cm² the valley current had increased to approximately 160 percent of its initial value and the peak current decreased by approximately 4 percent.

Power Output Drops

A 1-Gc cavity oscillator showed, for a given operating point, a power output decrease of 1.5 db per $10^8$ neutrons/cm², becoming inoperative at $10^9$ (see Fig. 2). A much more rapid rate of change was found for silicon units. At room temperature, the valley
current increased by a factor of approximately two for an exposure of $9 \times 10^7$ neutrons/cm$^2$.

R. A. Logan and A. G. Chynoweth of BTL irradiated several Esaki diodes with 800-Kev electrons and found the valley current rose quite rapidly until the negative resistance region of the device was entirely destroyed at integrated electron fluxes of the order of $10^8$ electrons/cm$^2$.

**How They Compare**

According to Bell researchers, this means tunnel diodes are somewhat, but not substantially, less sensitive to radiation than the least sensitive of other semiconductor devices. They point to the germanium diffused-base transistor which was reported to permit circuit operation up to $10^9$ neutrons/cm$^2$.

GE researchers feel, however, that tunnel diodes are still generally much more radiation resistant, as ordinary transistors are affected by $10^7$ neutrons/cm$^2$. On the other hand, they claim their 7077, 7462 and 7266 ceramic tubes have withstand $10^8$ fast neutrons/cm$^2$ without any observed permanent changes in their characteristics.

By way of reference, the Enrico Fermi Fast Breeder Reactor being built at Lagoona Beach on Lake Erie is designed to have an average effective core flux of $0.5 \times 10^7$ neutrons/cm$^2$/sec.

**European Combine To Produce Hawk**

_Hawk air defense_ guided missile system will be produced in Europe by a company jointly set up by five electronics firms in as many countries.

Under an agreement signed this month with U. S. Hawk prime contractor Raytheon, Setel (for Societe Européenne de Teleguidage) will get patent licensing rights and knowhow.

The European companies are Thomson-Houston, France; Finneccanica, Italy; Telefunken, West Germany; Ateliers de Construction Electrique de Charleroi, Belgium; and Philips, Netherlands.

Hawk production plans, which will give NATO its most advanced weapon system to counter air attack, will go ahead after additional agreements are signed by Setel with NATO's production organization and the five member national prime companies. Raytheon will assist in setting up the European production lines.

Recently, the Hawk scored the first interception and destruction of a ballistic missile when it demolished the larger Honest John.

Both missiles were traveling at supersonic speeds.

The arrangements for European production of Hawk are expected to set a pattern for production of new weapons for NATO.

**Telescope Cost Soars Over $100 Million**

Sugar Grove, W. Va.—Cost estimate on the world's largest radio-telescope now under construction has soared to $100,600,000, Capt. Frank C. Tyrrell, Navy officer in charge, said. The installation, known as the Sugar Grove Radio Research Station, is located about 75 miles northwest of Waynesboro, Va.

Tyrrell recalled that the first estimate of the cost was $79 million. He said the development of scientific and mechanical facilities never before attempted in a comparatively new field of research had caused the original estimates to be upped.

The Navy officer said that steel erection on the big dish will start by the end of this month. American Bridge Division of U. S. Steel has the $10-million contract for the steel now being fabricated.
The El Model 800 True Rms Digital Voltmeter

This revolutionary instrument incorporates a unique temperature stabilized diode network, operating on the square law principle, to yield a true rms voltage reading, regardless of the AC wave form or DC. No hot wire elements of any kind are used.

SPECIFICATIONS

- All-electronic, totally-transistorized
- 0.1% accuracy for crest factors up to two
- 0.1% response from 50 cps through 5KC and at DC
- Higher frequency response (at least 10KC) at reduced accuracy and for certain waveforms
- 3 second balance time, typical
- Calibration accuracy held for minimum of 30 days—typically much longer
- Automatic ranging

Accuracy: Within the range and frequency capability of the instrument, RMS value of crest factor not exceeding two will be indicated to ±0.1% of reading or two digits, whichever is greater.

The instrument accurately accounts for:
- Harmonic components: 50 cps to 5KC 0.1% or 2 digits
- Sinusoidal response: 50 cps to 5KC 0.1% or 2 digits
- Square wave: 50 cps to 1KC 0.1% or 2 digits
- Triangular wave: 50 cps to 1KC 0.1% or 2 digits
- DC (no polarity sense)

Accuracy maintained 30 days without calibration adjustment. Above accuracies after 45 min. warm-up time.

Range: Automatic ranging. 1 volt to 999.9 volts with manually selected 0.1 volt to 1 volt range.

Balance time: Typically less than 3 seconds. Maximum 5 seconds per range.

Temperature: 0° to 50°C.

Power: 60 cps, single phase, 125 watts

Dimensions: 19" wide x 8 3/4" high x 20" deep.

CLEVITE TRANSISTOR
WALTHAM, MASSACHUSETTS
NEW!

ADVANCED DESIGN POWER TRANSISTORS FROM CLEVITE

Three new lines of germanium power transistors by Clevite feature new advances in controlled gain spread, fully specified collector-to-emitter voltage characteristics and low current leakage — even at maximum voltages and high temperatures.

The new 8 ampere switching series can be used to replace the older, more costly ring-emitter types in 3 to 8 ampere service.

The new 25 ampere switching type offers exceptionally low saturation voltage and is available with either pin terminals or solder lugs.

The new Spacesaver design not only affords important savings in space and weight, but its significantly improved frequency response means higher audio fidelity, faster switching and better performance in regulated power supply applications. Its low base resistance gives lower input impedance for equal power gain and lower saturation resistance, resulting in lower “switched-on” voltage drop. Lower cut off current results in better temperature stability in direct coupled circuits and a higher “switched-off” impedance.

CLEVITE NOW OFFERS THESE COMPLETE LINES

Switching Types
- 5 ampere
- 8 ampere
- 15 ampere
- 25 ampere
- 3 ampere Spacesaver

Amplifier Types
- 2 watt
- 4 watt
- 2 watt Spacesaver

All Clevite germanium power transistors are designed for low thermal resistance, low base input voltage, low saturation voltage and superior current gain.

For latest data and prices or application assistance, write for Bulletin 60 . . .
A convenient low-cost method of testing tunnel (Esaki) diodes with nanosecond switching speeds is shown above. A Tektronix Plug-In Oscilloscope provides both the current ramp source for the tunnel diode and the pretrigger for the Type N Unit. The N Unit is set up in the usual way — however, the oscilloscope main sweep generator is allowed to free run at 1 µsec/cm. The + GATE OUT not only triggers the N Unit but also provides a delayed current ramp with a low rate of change — which allows the tunnel diode to switch at essentially its own rate.

The new Type N Unit converts your Tektronix Plug-In Oscilloscope to a Pulse-Sampling Oscilloscope with a rise-time of 0.6 nanoseconds. Applications in which the signal source can furnish a "pretrigger", such as that shown above, require no additional equipment.

For a completely versatile Pulse-Sampling System, Tektronix also manufactures a Pulse Generator and Trigger Takeoff, a 60-nsec Delay Line, a Pretrigger Pulse Generator, and several useful accessories. Please call your Tektronix Field Engineer for complete details and, if desired, a demonstration of the Type N Unit or the complete System.

Characteristics

- 0.6 nsec risetime (approximately 600 mc).
- 10 mV/cm sensitivity. (2 mV or less amplitude noise.)
- 1, 2, 5, and 10 nsec/cm equivalent sweep times (20 to 50 psec time noise).
- 50-ohm input impedance.
- 50, 100, 200, and 500 samples per display.
- Sampling rate — 50 c to 100 kc.
- ±120 mV minimum linear range (safe overload 4 V).
- Trigger input requirement: ±0.5 V, 1 nsec duration, 40 nsec in advance of signal. Recovery time is 10 µsec. Counts down from 50 mc.
- PRICE $600 f.o.b. factory.
LONG ISLANDERS LAUNCH SELF-HELP PLAN

INTERVIEWS THIS WEEK with electronics companies on Long Island reveal the growth of a regional awareness that is bringing new vitality to this once "depressed" island appendage to New York state. 

Industry expansion in the area began during World War II in support of the then booming aircraft production there. After the war, business activity declined sharply—dragging down with it the finances and morale of many small electronics companies.

A survey this week by ELECTRONICS reveals this: a greatly increased morale and much constructive activity and thinking are lifting the region by its bootstraps. Increased plant facilities, larger payrolls, more sales volume and other growth signs are readily evident (see survey table covering 35 firms).

Credit for this upturn is given basically to two instrumentalities: one is the formation of bidding teams in which a number of small firms go out after contracts too large for any of them to handle individually (ELECTRONICS, p 40, Feb. 20, 1959). The other is the formation of a strong trade association aimed at promoting regional loyalty and industry potential.

Presently the fastest-growing trade organization on the island, the Long Island Electronics Manufacturers Council numbers 56 companies, with more now on the way. Membership includes such corporations as Republic Aviation, Sperry Gyroscope, Sylvania, as well as medium companies and small firms having as few as 18 employees in 4,000 sq ft of plant space.

Many Handicaps

Spokesmen from member companies of LIEMC point out there are many handicaps to their aims. The president of a major component company says a good bit of the trouble is political. "In such heavy electronics states as California and Massachusetts, voices can be raised at the federal level in matters affecting the industry, but there is no senator from Long Island."

A test equipment manufacturer adds this comment: "Here on the island, there is no institute of higher learning to act as a rallying point. No MIT or UCLA."

A number of LIEMC members are working to remedy this particular shortcoming via an assistance program with Garden City's Adelphi Research Center. Funds and technical assistance being channeled into the center will someday make it a focal research site, according to its supporters.

Another obstacle Long Island electronics men have to overcome is the competition and political attention of the rest of New York state. Such major electronics centers as Rochester, Schenectady, Syracuse and others are vital factors in the way Long Island's industry can grow.

*Source: Survey by Long Island Electronics Manufacturers Council
Despite these handicaps, electronics has become Long Island's number one industry. There has been a step-up in inter-company liaison, a closer look at local suppliers before purchase orders are written, and an increase in regional subcontracting.

Some credit for this is given to what the president of a systems producer calls "the second generation of electronics men."

The new executives aren't content to sit back and wait for orders. They are going out after contracts, visiting each other's plants and bringing vitality into the whole area.

Bid Combinations

One group recently formed to stimulate trade is the National Electronics Facilities Organization, Inc. Of the seven member companies, all but two are headquartered on Long Island. The five L. I. firms are: Dade Associates, Garden City; General Transistor, Jamaica; Servo Corp. of America, Hicksville; Specialty Electronics Development Corp., Syosset, and Technical Research Group, Syosset.

The purpose of this joint venture is to bid for government work at prime contractor levels. NEFO has combined assets of nearly $30 million and had 1959 sales of $61 million. In the aggregate it has more than 4,000 employees (including 30 Ph. D's). President this year is Henry Blackstone of Servo Corp.

Within the next 30 days the group expects to submit bids on contracts. A NEFO spokesman tells ELECTRONICS seven bids will be made on military, commercial and government agency work.

Members of LIEMC include:

Pliers for electronic work are Utica's specialty. With over 1000 different types of pliers in stock, Utica has become the leading supplier to the electronic industry. As plier specialists, Utica can recommend and supply the right tool for the job. To you, the right tool means better, easier work and lower costs. In plant after plant throughout the country, engineers and purchasing men are turning to Utica. Why don't you?

WESCON NAMES BEKINS
Official Mover for 1960 Wescon Show

By using Bekins Certified Service for moving your exhibit and machinery to and from the WESCON Show, you will not only simplify your move but save money on local Los Angeles transfer as well.

For complete shipping information, please refer to your WESCON Exhibitor Service Bulletin, or write Ellis Gordon, 3625 South Grand Avenue, Los Angeles 7, California.

ELECTRONICS MOVING BROCHURE NOW AVAILABLE
New brochure describes the Certified Services and new Electronics Vans used exclusively by Bekins. For your free copy write Bekins Electronics Moving Division, 3625 South Grand Avenue, Los Angeles 7, California.
Cornell-Dubilier now combines highest purity aluminum foil with a patented cleaning process to eliminate all impurities in making electrolytic capacitors for power supplies and control circuits in military and industrial computers, electronic controls and other high-reliability electronic equipment. The process, specially developed for Type FAH high-reliability capacitors, achieves a freedom from corrosion that heretofore was considered impossible in foil-type electrolytics. This combination of highest-purity foil with complete freedom from contaminants also assures you that C-D electrolytic capacitors will have low leakage current and long shelf life. For complete engineering data, write for Bulletin 538 to Cornell-Dubilier Electric Corporation, South Plainfield, New Jersey. Manufacturers of consistently dependable capacitors, filters and networks for electronics, thermonucleonics, broadcasting and utility use for 50 years.

**SPECIFICATIONS AND FEATURES**

- Heavier tabs and longer staking lengths for excellent current-carrying characteristics.
- Hermetically sealed, aluminum cans with molded cover. Also available with outer insulating tube of wax-impregnated Kraft board or plastic.
- Hermetically sealed with Hycar rubber gaskets.
- Tapped terminal inserts or solder lug terminals.
- Standard diameters: 1 3/4", 2", 2 1/4" and 3".
- Can height: 4 1/4".
- Voltages: 3 to 450 VDC.
- Capacitances: to 65,000 mfd. depending on voltage.
- Temperature range: -20°C to +85°C.
Unmatched for MIL-R-11 APPLICATIONS

Today's best looking resistors are every bit as good as they look. Going beyond MIL-R-11 requirements, Coldite 70+ Resistors give important dividends in terms of load life, moisture resistance and other important characteristics.

Unmatched for EASY SOLDERING

Thanks to an exclusive extra solder coating applied after the usual tin dipping, Coldite 70+ Resistors solder readily by any method—dip or iron. Leads stay tarnish-free and solderable even after months in storage.

Automatic Weather Station

TRAVELS BY HELICOPTER

By FRANK JACOBS
Project Engineer, Specialty Electronics Development Corp., Syosset, N. Y.

A NEED FOR MEANS of gathering meteorological information in mountainous and other impassable areas has led to development of a completely automatic and easily transportable weather station.

The station was made by Specialty Electronics Development Corp. for the Army Electronic Proving Grounds at Fort Huachuca, Ariz. Its essential characteristics are automatic operation and mobility—plus its ability to operate for months without attention.

Records, Transmits Data

The station records data and then, when called upon by a central point, transmits the readings by radio or wire line.

Each station, weighing less than a ton, is housed in a standard shelter designed for lifting by helicopter.

The weather report consists of a station identification number, free air temperature, dew point temperature, wind direction, wind speed, air pressure, precipitation.

The accuracy of the apparatus is confined to the following limits:
Air Temperature ±1.5 degrees F; dew point temperature ±3 degrees F; wind direction ±5 degrees; wind speed ±5 knots (5.77 mph); air pressure from 650 to 1050 millibars ±0.33mb; precipitation ±0.02 in.

Weather-gathering equipment is connected by electrical cables and capillary tubing to the termination panel and then to the coder panel. The latter panel accepts converted analog to digital data from printed boards for wind direction, air temperature, dew point temperature and air pressure. A clamping circuit fixes the data momentarily, and a master stepping selector switch picks up the information.

Series of Steppers

In the case of wind speed, the data is the average over a period of one minute, recorded on a separate series of steppers. Rainfall is also accumulated by means of digital steppers, but for the entire period between readouts.

As the master stepper scans the variously collected data, the digital information is transformed into a code acceptable to the teletypewriter, by means of a diode matrix. The diode matrix connects to the transmitter-distributor panel and then to the converter panel and transceiver for transmission to the teletypewriter of the central station.

The system is not limited to the data listed, but can be adapted or expanded for the recording of cloud ceiling heights (ceilometer), atomic radiation detection, ground temperatures, or seismographic tremors.

The recording is done through a standard teleprinter code. The meteorological parameters are measured and coded at the remote locations and are received on a Teletypewriter TT-8/FG at the central station. Provision is made for service checking at the various stations, by means of an identical teletypewriter.

The remote stations are selected by means of an automatic triggering system, consisting of a Hupps Electronics Co. (ERX) sender selector connected through a converter to a radio transmitter or to a wire line.

Each remote station is provided with a receiver selector.

The operator of the central station presses a numbered button corresponding to the remote station identification, and the selection is made automatically by means of a selective code. Control is had of "group" or "individual" stations. Alerting all stations and turning on wind speed reading is done by group.

Readout is accomplished by individual station.

The central station is relatively simple, consisting only of the radio link, converter, teletypewriter transmitter and control.

HAS THE RIGHT SILICON EVERY POWER-HANDLING CHOICE TO FIT YOUR NEEDS VOLTS

Since its introduction in 1957 by General Electric, hundreds of firms have successfully incorporated G-E Silicon Controlled Rectifiers into their products. The impact of this revolutionary device that not only rectifies but controls current is growing every day. Volume production of a wide range of SCR types is now a reality at General Electric.

G.E.’s medium-current C35 Series provides blocking voltages to 400 volts and load currents to 16 amperes. The high-current C60 Series goes to 300 volts and 50 amperes; low-current C10 Series 400 volts and 4 amperes. The C10 Series has ratings identical to C35, but is specially selected to furnish guaranteed fast turn-off time for inverter circuits. The C36 Series has ratings lower than C35, with currents up to 10 amperes. The C60 features an all hard-solder design for a high degree of freedom from thermal fatigue.

New SCR Application Manual presents all significant design information developed to date and many new circuits. Your G-E Semiconductor Sales Representative also has complete application data. Many authorized G-E Distributors now stock Silicon Controlled Rectifiers for fast delivery at factory prices in quantities up to 100.

NASA announces...

THE TRANSFER OF THE DEVELOPMENT OPERATIONS DIVISION OF THE ARMY BALLISTIC MISSILE AGENCY TO THE NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

Dr. Wernher von Braun, director of the new NASA Marshall Space Flight Center in Huntsville, Ala., pictured with NASA's Mercury Astronauts

Dr. Wernher von Braun and his space team join NASA

The National Aeronautics and Space Administration leads the nation’s efforts to find, interpret and understand the secrets of nature as they are revealed in the laboratory of space.

This vigorous effort requires boosters for space vehicles which greatly exceed the thrust of any boosters currently available. For this reason, the $100 million Huntsville plant, together with its famous space team, are being transferred to NASA. The new NASA facility in Huntsville will be known as the George C. Marshall Space Flight Center.

NASA is now the largest civilian research organization in the United States. For details about outstanding professional opportunities, address your inquiry to the Personnel Director of any of these NASA centers:

NASA Goddard Space Flight Center

ultra-high precision capacitors

Southern Electronics high-precision capacitors are demonstrating their proven reliability today in twelve different missiles, analog computers, and many radar and communications applications.

SEC high-precision capacitors utilize polystyrene, providing .01% tolerances, and mylar and teflon to meet .5% requirements. They show excellent stability characteristics over an extended temperature range, and tolerances are unaffected even at extreme high altitudes.

The unusual accuracy, stability and reliability of SEC capacitors are the result of engineering experience concentrated on the design and manufacture of precision capacitors only, plus rigid quality control standards subjecting each capacitor to seven inspections during manufacture, plus final inspection.

Our engineering experience enables us to meet your size requirements, while holding to exact capacitance and tolerance specifications.

SEC capacitors are manufactured in a wide range of capacitance to meet your needs from 100 mmfd. to any higher value, and meet or exceed the most rigid MIL-SPECS.

Write today for detailed technical data and general catalog.

Japan Ponders Export Policy

Nippon manufacturers fear government will set a quota for transistor radios to U.S.

TOKYO—Japanese transistor radio manufacturers fear the government will impose a quota system on their exports, it was learned last week.

The manufacturers had asked MITI (Ministry of International Trade and Industry) to approve a reduction in the export floor price from $14 to $11. They expected to put lower price schedules into effect April 1, but MITI held up approval until April 11.

As a result of the government's delay, many U.S. orders placed in anticipation of lower prices were canceled and prospective buyers held off.

Makers In 'Squeeze'

Although MITI explains the delay officially as a "matter of procedural routine," industry sources note that some government officials have been advocating a quota system along with the price changes. Observers feel the government has now given a conditional go-ahead and may impose the quota system if the floor price is violated.

Now some Japanese manufacturers find themselves in a "squeeze" because they have been exporting to the U.S. standard model transistor radios (six or more transistors) for as low as $9 a set.

From April 1 to April 16 the rush by manufacturers to apply for export licenses covered 400,000 units. The number of sets covered by applications this month was expected to reach 600,000.

Both MITI and the Japanese Foreign Office now fear that if permission is granted to export more than 500,000 sets monthly to the U.S. the result may be an intensification of American moves to restrict Japanese transistor radio imports, as well as throw the highly competitive domestic industry into confusion.

The opinion seems to be gaining ground in government circles that some check on the transistor radio exports is necessary, either control of the quantity or a temporary suspension of export permits.

Industry spokesmen have said they oppose any quantitative control, regard it as running counter to general foreign trade liberalization trends. They contend that the

Magnetic Unit Attracts Students

Two-ton magnetic unit is studied by Levittown High, N.Y., student members of JETS (Junior Engineering Tech Society), who will use it in a cyclotron they are building. JETS is a nationwide group sponsored by industry and education.
1-million-sets-plus a month that they exported last year to the U.S. did not bring restrictive measures because the exports merely met or-ders. These sources assert that this year’s big rush for export applications by Japanese companies was stirred by foreign buyers who placed large orders in expectation of lower prices.

*Expect Stabilization*

The industry spokesmen add that they believe Japanese export of transistor radios would be stabilized at 500,000 units a month anyway in “due course.”

Meanwhile, Sony president Masaru Iouka, who returned last week to Tokyo from a U.S. visit, said one of the most promising export items for the U.S. market this year is transistor tv. He noted that inventories of transistor radio sets in the U.S. were “rather high.” Industry sources also predict a pickup in exports of tape recorders this year, noting that Japan exported about two-thirds of the 70,000 units shipped to the U.S. from abroad last year.

**New High-Speed Fax For Weather Maps**

U.S. WEATHER BUREAU is completing installation of advanced, high-speed facsimile recording equipment for its high-altitude weather map network.

Equipment produced by the Alden Electronic & Impulse Recording Equipment Co., Westboro, Mass. is expected to be in operation soon at all network stations located throughout the U.S., including Alaska, Hawaii, and Puerto Rico. Last June the first units went to weather stations at Suitland, Md., and New York’s Idlewild Airport.

The system, which provides comprehensive jetstream data to trans-oceanic aircraft, can now transmit 120 lines a minute, the Weather Bureau says. However, Alden reports its equipment is capable of up to 900 lines a minute with higher capacity lines but without reengi-neering. The company says its flat-copy scanners permit continuous scanning of any size map without cutting because map doesn’t have to fit the size of a scanner drum.

**RADIO INTERFERENCE — FIELD INTENSITY MEASURING EQUIPMENT, 375 mc to 1000 mc**

The NEW NM-52A RI-FI instrument developed by STODDART to government specifications is now ready for immediate delivery.

Its purpose is to investigate, analyze, monitor and measure to the highest practical degree conducted or radiated electromagnetic energy to military specifications within the frequency range of 375 mc to 1000 mc. In addition, the NM-52A is valuable as a highly sensitive frequency-selective voltmeter and receiver for numerous laboratory and field applications.

**OUTSTANDING FEATURES**

- **SENSITIVITY OF 1 MICROVOLT ACROSS 50 OHMS**, provides up to 40 db more than Military Measurement Requirements.
- **SINGLE KNOB TUNING.**
- **RAINPROOF, DUSTPROOF, RUGGEDIZED AND TOTALLY ENCLOSED**, for all-weather field use or precise laboratory measurements.
- **NEW BROADBAND ANTENNA**, for rapid detection and measurement of radiated energy over entire frequency range.
- **NEW POWER SUPPLY, 0.5% REGULATION**, for filament, bias and plate voltages, and also for use as a standard laboratory power supply.
- **OSCILLATOR RADIATION LESS THAN 20 MICRO-MICROWATTS**, over 20 times better than Mil-Specs require.
- **TWO DECADE LOGARITHMIC METER SCALE**, increases range of voltage measurement without change of attenuator steps.
- **THREE DETECTOR FUNCTIONS**, for peak, quasi-peak or average measurements.
- **PORTABLE OR RACK MOUNTING**, no modification required for laboratory, mobile, airborne or marine installation.
- **I-F OUTPUT FOR PANORAMIC DISPLAY OR NARROW BAND AMPLIFICATION**, for visual presentation or increased sensitivity.
- **OVER 100 DB SHIELDING EFFECTIVENESS**, increases measurement capabilities in presence of strong fields.
- **VISUAL PEAK THRESHOLD INDICATOR**, for accurate slide-back peak voltage measurements.
- **CONSTANT BANDWIDTH OVER ENTIRE FREQUENCY RANGE.**

The NM-52A now joins the family of STODDART government approved RI-FI instrumentation covering the frequency range of 30 cps to 10.7 kmc to provide the finest RI-FI measuring equipment.

X-15 part flies first 3000 miles by Air Express

The scene: Edwards Air Force Base, Calif. Crack engineers work 'round the clock to ready the X-15 for its flight to the brink of outer space. Its engine, built by Thiokol in Denville, New Jersey, packs a 400,000 HP punch—more than the power of two giant ocean liners! Because of an accelerated assembly schedule, some parts—like this turbine pump control—are installed right on the flight line. They must be shipped fast, with kid-glove handling. In short, a job for low-cost AIR EXPRESS. Give your business these advantages, too. Call AIR EXPRESS to speed your products FIRST TO MARKET . . . FIRST TO SELL.
NEW PROTECTION AND COST SAVINGS

with VICKERS® CAPTIVOLT™

SURGE PROTECTORS for Silicon Rectifiers

GUARD SILICON RECTIFIERS AGAINST BREAKDOWN FROM TRANSIENT HIGH VOLTAGES
REDUCE INITIAL RECTIFIER COST

To protect silicon rectifiers against destructive voltage surges, design engineers are using rectifiers rated considerably higher than the normal operating level. This is a costly practice, and doesn’t always guarantee reliable rectifier performance and freedom from breakdown.

The new Vickers CAPTIVOLT Surge Protector, with its non-linear resistance characteristics, eliminates the need for extreme derating of cells...assures greater reliability and longer rectifier life. Connected across the secondary of the transformer supplying AC to the rectifier circuit, the CAPTIVOLT absorbs excessive intermittent energy up to 3000 watts. Extreme decrease in CAPTIVOLT resistance with small increase in voltage shunts destructive voltages...protects the rectifier. Under normal operating voltages the high resistance of the surge protector consumes less than 5 watts.

The CAPTIVOLT has been field tested for more than a year, laboratory surge tested for more than 20,000,000 cycles.

AN EXAMPLE OF THE COST SAVINGS WITH THE NEW VICKERS SURGE PROTECTOR

New high-speed research micro-microammeter

Model 415 offers high speed of response, accuracy, and zero suppression.

The new Model 415 incorporates advanced high-speed circuitry developed by Keithley Instruments for rocket and satellite experimentation — where measurements of Lyman-Alpha night glow and upper air density require fast response.

A speed response of less than 600 milliseconds to 90% of final value at $1 \times 10^{-12}$ ampere is possible where external circuit capacity is 50 picofarads ($\mu\text{F}$). Critical damping of the circuit, with any input capacity, is maintained on all ranges through one infrequent adjustment. There is no possibility of oscillation or poor response, on any range.

Accuracy is $\pm 2\%$ of full scale on $10^{-3}$ through $10^{-8}$ ampere ranges, and $\pm 3\%$ of full scale on $3 \times 10^{-9}$ through $10^{-12}$ ampere ranges.

The 415 also provides zero suppression up to 100 full scales, permitting full scale display of one percent variations of a signal. Once suppressed to zero, such variations may be observed on any of the next four more sensitive ranges without resetting the suppression.

Excelling other Keithley 400 Series Micro-microammeters in speed of response, the 415 is ideal for current measurements in ion chambers, photomultipliers, gas chromatography, mass spectrometry.

CLEVELAND 6, OHIO

PRICE: Model 415, $750.00
Israel Forms Electronics Group

Seeks to attract foreign investors and expand production activities. Government giving full support to new move

TEL-AVIV—Government, local scientific institutions and all manufacturers of electronic devices have decided to join forces in an effort to facilitate the industry's expansion and enable it to gradually cover all requirements of the Israel market.

An Electronic Manufacturers Association, incorporating 21 manufacturers, has been established. The Hebrew University, the Israel Institute of Technology and the Weizman Institute of Science and the Standards Institution are advisory members.

What's Planned

Defense Ministry and Trade and Industry Ministry will back the Association, whose plans call for:

1. Contacts with the U. S. Operations Mission aimed at securing the assistance of foreign experts in research problems and having Israel engineers participate in research and industrial projects in the U. S.

2. The introduction of a quality control system evolved in cooperation with the Standards Institution where a laboratory will go into operation in the near future.

Some 80 electronic engineers are turned out each year by the Israel Institute of Technology. Besides, technicians are trained at six vocational schools offering four-year courses. Many of the school graduates are inducted into the Armed Forces as electronic technicians and undergo additional training.

Output: $6 Million

The industry is still in its embryonic stage and its global output does not appear to exceed $6 million a year.

Items produced include: radio receivers, transistors, amplifiers, switches, capacitors, tape recorders, pickups, tube testers, signal generators, inter-communication systems, high-frequency dielectric heaters, fire and burglar alarm systems, X-ray apparatus.

Lately some agreements have been concluded with foreign firms with a view to extending the range of products, partly in order to meet some of the demand of electronic equipment for defense and the postal services.

To Make TV Parts

The industry is also getting ready to manufacture parts for tv sets in anticipation of a government decision to erect a tv transmitter.

In view of the available skilled know-how and labor force, the electronics industry here will try to attract foreign investors and engage in production of more devices.

Expanding Market

X-ray analysis equipment will find an expanding market in the field of product control.

That's the prediction of Philip I. Wolf, manager of product specialists for Philips Electronic Instruments, Mt. Vernon, N. Y. Wolf says his firm has noted a marked increase in industry's interest in applications of X-ray analytical instrumentation.

Fuel Cell Power

Portable power pack using 20 ion-membrane fuel cells and weighing about 30 lb is reported by GE to be under development for Marines and Army. Cutaway shows cell setup.
These Sorensen a-c and a-c/d-c testers completely cover the voltage range from 0-150,000 vac and 0-300,000 vdc with current capacities as high as 4000 milliamperes a-c (plus 5 milliamperes d-c for the a-c/d-c units).

All components are conservatively rated to insure maximum life and top performance. Maximum rated current can be drawn continuously over the entire output range and overloads may be supplied for a short time to "burn" faults. Easily reversible d-c polarity of a-c/d-c testers.

**New Catalog.** Just off the press, Sorensen's new 32-page catalog gives technical data on the complete line of Sorensen a-c and a-c/d-c testers as well as on Sorensen h-v d-c supplies, h-v electrostatic generators, low-voltage d-c power supplies, a-c line-voltage regulators, and frequency changers. Extensive power supply application data is also given. Write for your copy today. Sorensen & Company, Richards Ave., South Norwalk, Conn.

---

**Safe. Easy to operate.**

Rate of voltage application conforms to ASTM standards. Portable models. Floor mounted models.
DESTINATION KNOWN

When a mighty "Thor" soars from Vandenberg Air Force Base, equipment designed and built by Packard Bell checks it out, launches it and predicts its point of impact.

ENGINEERING BEYOND THE EXPECTED

The Missile Impact Predictor is one-eighth the size and was built at one-tenth the cost of previous systems. Ground support equipment matches the reliability built into the "Thor." All combine to guarantee an effective weapon for retaliation or space exploration… destination known.

...and now, COAXICON fits a wider range of cable sizes

COAXICON offers not only the fastest method of attaching disconnects to your shielded wire...it is not only the most reliable disconnect you can buy—for either free hanging or panel mounted applications...not only the most economical on the market...but...COAXICON now fits shielded cable sizes up to 1/4" O.D. with interchangeable contacts that permit a wide variation of inner conductor diameters in each cable size.

Further, COAXICON mounting clips accommodate a wide range of panel thicknesses for through-panel applications. Whether your requirements include RG type coaxial cable, standard coaxial cable or other shielded cable types, with solid or stranded conductors, look to AMP for the precise Coaxicon Disconnect you need.

If you're not now using the A-MP Coaxicon, send for literature today. It can solve many shielded circuit problems for you.
SEQUENTIAL RECEIVERS FOR
French Color Tv System

Henri de France method for compatible tv features simple chrominance circuit. System uses sequential transmission of chrominance and employs one-line memory in receiver.

By ROGER CHASTE,
Compagnie Générale de TSF, Paris, France;
Pierre Cassagnes and MARCEL COLAS,
Compagnie Francaise de Télévision, Paris, France

Bandwidth occupied by a black and white television signal depends on the number of lines used. This number corresponds to a given vertical definition, and it is natural to demand the same definition in the horizontal direction.

Thus, a given number of horizontal spots are made to correspond to a given number of lines and so the duration of a point is finally related to some bandwidth. Since the eye requires less definition for the color information than for the luminance information, it is proper to distribute the decrease in definition between the horizontal and vertical directions. In the Henri de France (HDF) system this is done through time multiplexing of the two chrominance signals.

At the transmitter, only the Y signal and one of the chrominance signals are transmitted at every instant. At each line, the transmitted chrominance signal is permuted. In short, the color is analyzed with the number of lines cut down by half, while the total number of lines is retained for the black and white.

At the receiver, which is examined in detail later, there are only two signals available at any instant, while three are necessary for reconstructing a color picture. To get three signals, use is made of the two signals available at that instant and the chrominance signal that was transmitted in the preceding
line. Thus, the three signals are made available by taking advantage of the fact that the eye is incapable of discerning color variations from one line to the next. From one frame to the next, the type of analysis changes for each line. A line analyzed in blue for one frame is analyzed in red for the next.

By time multiplexing of the chrominance signals, a single signal is added to the luminance signal to secure the transmission of a color picture. This single additional signal is then used to modulate a subcarrier whose frequency is situated at the end of the spectrum of the luminance signal Y. Using a process which is now classical, the visibility of this subcarrier is lowered to a frequency that is equal to an odd multiple of half the line frequency. In the first version of the HDF system the subcarrier is amplitude-modulated. Thus, the quality of color reproduction is entirely independent of accidental phase variations. This ensures great ease of transmission, particularly over long radio links.

The transmitted signal is different from one line to the next as shown in Fig. 1. Figure 1 corresponds to the case in which the chosen chrominance signals are R-Y and B-Y. The picture transmitted is the test pattern of color bands consisting of a white band, a black band, 3 bands corresponding to the primary colors red, green and blue, and 3 bands corresponding to their complementary colors of yellow, cyan and magenta.

The figure shows the superposition of the amplitude-modulated subcarrier on the stepped signal corresponding to luminance. A given color is defined by the combination of the two subcarrier amplitudes corresponding to two successive lines.

Figure 1 also shows the presence of a nonmodulated subcarrier on the back porch of the R-Y line. This burst is used at the receiver to identify the chrominance signal transmitted.

The experimental receiver shown in Fig. 2 has been designed for band III (174-216 Mc) while in Europe generally and more particularly in France, proposed bands for color television are IV and V (470-960 Mc). The number of lines used is 625. Frequency of the chrominance subcarrier is 4.43 Mc and that of the sound subcarrier is 5.5 Mc. Sound is frequency modulated.

In the receiver (Fig. 2), the r-f amplifier, the mixer, the i-f amplifiers for sound and picture are similar to those used in a black and white receiver. Just a few precautions are taken in the picture channel so that the elimination of sound does not cause a disturbance on the color subcarrier whose frequency is close to that of the sound carrier.

It is mainly after picture detection that the receiver takes up a special aspect due to the color television system used. After first being amplified, the chrominance signal is extracted by filtering from the complete picture signal (luminance + chrominance). This signal is fed to three parallel channels.

The first channel provides both a given amplification and a delay equal to the duration of one line. The second channel amplifies without introducing any delay. These two channels are then switched at line frequency towards two specialized detectors, one detecting the

COMPATIBLE COLOR TELEVISION

To make a color television system compatible, one of the electrical signals corresponding to the color picture has to be the same as that given by a simple black-and-white analyzer. This signal, generally denoted Y, is the so-called luminance signal. It is the signal which gives the color picture its definition. It occupies the normal bandwidth corresponding to the tv standard used.

Color can be reproduced at the receiver by two complementary signals, one corresponding to red, R, for instance, and the other to blue, B. For convenience, other complementary signals may be chosen.

Because of the physiological properties of the eye, color signals can be transmitted over a much narrower band than the Y signal. This spectral property corresponds to the fact that the eye is unable to distinguish the color of details, and that these details are provided with all the information in black and white which the eye can make use of.

In any color television system the three signals have to be multiplexed. One of them, the luminance signal Y, has to be transmitted wideband and without transposition, to ensure compatibility. A wider range of methods can be used for the other two colors.
R-Y signal and the other detecting the B-Y signal. This operation is shown diagrammatically in Fig. 3.

Figure 3A corresponds to the case of line \( n \) being analyzed at the transmitter in R-Y. In this case the signal B-Y is that of the preceding line \((n - 1)\) delayed by the duration of one line. Figure 3B corresponds to the next line \((n + 1)\) analyzed in B-Y. By means of the switch, at every instant the two signals can be passed to the appropriate detectors.

The third channel (Fig. 2) identifies at every instant the nature of the chrominance information transmitted, providing means for operating the switch. This identification relies on the use of the few subcarrier cycles present on the back porch of the R-Y lines.

The subcarrier pulsed signal also allows compensation of the d-c component of the chrominance signals and blocking of the chromatic channel when the chrominance signal level is too low (color-killer).

The chrominance circuits are shown in Fig. 4. The untuned primary of transformer \( T \), is inserted in the anode circuit of the first video amplifier tube. The low-Q tuned secondary drives the grid of the pentode section of \( V_\text{a} \). Potentiometer \( R \), in the screen circuit provides for the manual adjustment of the gain of the chrominance chain.

This saturation adjustment is the only chrominance adjustment available to the viewer. Anode circuits of \( V_\text{a} \) match the tube to the low input impedance of the delay line. The latter (see photo) is of the ultrasonic type and consists of a fused silica block of suitable dimensions to cause a delay equal to the duration of one line (64 \( \mu \)sec).

The transducers are small piezoelectric wafers of barium titanate. They convert the voltages to mechanical vibrations in tension. Transformer \( T \), matches the low output impedance of the delay line to the input impedance, \( V_\text{a} \).

Undelayed signals are collected on potentiometer \( R \), which is set up at the delay line input. This potentiometer also equalizes the voltages on the two channels. After amplification by \( V_\text{a} \) and \( V_\text{b} \), the direct and delayed signals are transmitted to the switching system by transformers \( T \).

The switch consists of silicon diodes \( D_1 \), \( D_2 \), and \( D_3 \), which, depending on their bias conditions, conduct or cut off the signals to transformers \( T \). Through the effect of this switching, the subcarrier modulated by signals B-Y appear only at the secondary of the upper \( T \), transformer and the subcarrier modulated by signals R-Y appears

**Fig. 3**—Operation of switching system is simplified by using one-line memory.
only at the secondary of lower $T$ transformer.

After detection by silicon diodes, the R-Y and B-Y signals are filtered and amplified by the two sections of $V_5$. Each resistance amplifier is provided with inductive compensation and a cathode negative feedback. The output voltages are applied to the R and B guns of a three-color tube through the arrangement for compensating the d-c voltages.

Also, the matrix of $R_p$, $R_s$, and the 270K between them restituates the green signal which is then dealt with in the same manner as the R and B.

Switching voltages are supplied by monostable multivibrator $V_{sa}$ and $V_{sb}$. They are transmitted to the switch through high-value capacitances. The multivibrator is controlled by a pulse which identifies the chrominance signal in every other line transmitted. This pulse is obtained as follows.

A few cycles of the subcarrier are transmitted only on the back porch of the lines corresponding to red. The complete signal is passed to tube $V_4$, which acts as an open gate for the duration of the back porch. The gate is opened by positive pulses from the line sweep transformer and passed to the screen of $V_4$. Thus, a pulse of a few subcarrier cycles is collected at $TB$, during every other line. This pulse is detected and used to control the switching diodes through the monostable multivibrator.

After detection, the chromatic signals possess a d-c component which is not zero in the absence of chrominance. This component is proportional to the amplitude of the unmodulated subcarrier. It is compensated by a d-c voltage of equal value and of opposite sign obtained by integrating the chrominance synchronizing pulses. Integration is obtained by diode $D_e$ and capacitor $C_e$.

For extreme reception conditions it may be useful to suppress the chrominance subcarrier automatically to get only a black-and-white picture. Automatic suppression is secured by cutting off tubes $V_{sa}$ and $V_{sb}$. When the amplitude of the subcarrier becomes too low, the chrominance synchronizing pulse is no longer capable of triggering the multivibrator. Under this condition $V_{sa}$ and $V_{sb}$ are cut off.

The only special element in the circuits is the delay line. Its price, based on monthly production of 500 units, is $16. Mass production would substantially reduce this.

Counting and Timing Circuits

USE SATURABLE REACTOR

Operating primarily as frequency dividers, adjustable timing circuits use a controlled rectifier and a saturable reactor.

Division by 10 is possible when the supply frequency is 400 cps

By J. S. SICKO
Light Military Electronics Department,
General Electric Co.,
Johnson City, New York

When a d-c voltage is applied to the control winding of a saturable reactor, a finite time will elapse before the magnetic flux reaches its final value. This time delay characteristic is used with a controlled rectifier in the circuit to be described to form what is essentially a frequency divider. At a supply frequency of 400 cps, for example, division by 10 or less is possible. Thus, the output is one pulse for every ten cycles—or other preset number of cycles—of the supply.

The timing circuit is shown in Fig. 1. Winding $N_i$ of the saturable reactor is excited with direct voltage $E_b$ and is in series with the gate of the controlled rectifier. When the saturable reactor is driven into positive saturation, the gate of the controlled rectifier has a large enough signal to turn on the controlled rectifier, provided the anode voltage is going positive with respect to the cathode.

For the output pulse to be repetitive, the flux in the saturable reactor has to be changed in the negative direction. This is accomplished by winding $N_i$ of the saturable reactor, which is in series with the anode, and thus the load of the controlled rectifier. After the controlled rectifier has been turned on, the voltage across $N_i$ is used to change the flux in the saturable reactor in the negative direction.

With the flux changed in the negative direction, the operation of the circuit to turn on the controlled rectifier can be repeated. Repetition rate in the controlled rectifier output circuit will be $1/n$ of the supply frequency, with $n$ (an integer) easily adjusted by varying $E_b$.

The circuit will be explained by considering its four separate modes of operation, modes that correspond to the four sides of the loop that the magnetic core traverses. Fig. 2A shows an ideal BH loop on which the various modes are indicated.

In mode $A$ operation, flux in the saturable reactor is being changed in the positive direction; in mode $B$, the reactor is saturated but the controlled rectifier has not been turned on. Mode $C$ occurs when the controlled rectifier is turned on and the saturable core is driven from positive saturation to a point where the flux can be changed in the negative direction. Mode $D$ occurs when the flux is changing in the negative direction.

The time delay of the circuit is obtained during mode $A$ operation and is the time required to move from point 1 to point 2 of Fig. 2A. With the controlled rectifier not conducting, the impedance in series with $N_i$ is high and this circuit is essentially open. When the bias voltage is applied to $N_i$, the voltage induced in the coil is $e = N_i x$.
FIG. 2—Stages of reactor cycle are defined in (A) Equivalent circuit for mode A in (B); waveforms in various parts of the circuit (C); equivalent circuit for mode C (D); equivalent circuit for mode D (E). During the conducting pulse, the voltage available for reset is shown as \( V' \) in (F). Output pulse rate as a function of bias voltage (G).

Using differentials, \( \Delta t = N_t \times 10^{-5} \Delta \phi / e \). Because \( e \) must equal the applied bias voltage \( E_h \), which is constant and not a function of time, the preceding equation defines the time delay available as the flux is changed in the core.

The equivalent circuit for mode A operation is given in Fig. 2B. For this period, the current in the controlled rectifier anode circuit is practically zero. Thus \( R' \) — the reflected load resistance — is much greater than \( R \), and \( i_t \) is approximately zero. The gate current for mode A is given by Eq. 2 of the design box. The value of \( H_c \) in Eq. 2 depends on the frequency at which the saturable reactor is being driven into saturation.

After the flux level in the saturable reactor has reached position 2, Fig. 2A, the gate current \( i_t \) is limited primarily by the resistance of the gate circuit. This value of gate current places the operation of the saturable reactor at position 3. The gate current now is large enough to turn on the controlled rectifier. However, the controlled rectifier will not be turned on during this time because the anode voltage is negative with respect to the cathode.

Circuit operation will be considered only when the saturable reactor saturates during the time when the anode to cathode voltage of the controlled rectifier is going negative. The operation of the circuit during Mode B illustrates a significant advantage of the timing circuit. The saturable reactor can be driven into positive saturation anytime between \( T_3 \) and \( T_4 \), Fig. 2C and the circuit will still operate properly. Therefore, small variations in \( E_h \) and core parameters do not affect the time that the controlled rectifier is turned on.

During mode C, the saturable reactor is being driven from point 3 to point 4, Fig. 2A, and remains in saturation. This mode of operation is completed during a small period compared to one-half cycle of the supply voltage.

Equivalent circuits for the load current and gate current are given in Fig. 2D. There is no coupling be-
Design of Timing Circuits With Saturable Reactors and Controlled Rectifiers

Mode A—Controlled rectifier off, flux is being set in the positive direction in saturable reactor.

\[ i_L = 0 \quad (1) \]
\[ i_s = \frac{H_{1s}}{0.4} \quad (2) \]

Mode B—Controlled rectifier on, saturable reactor in positive saturation.

\[ i_L = 0 \quad (3) \]
\[ i_s = E_B/R_L \quad (4) \]

Mode C—Controlled rectifier off, saturable reactor in positive saturation.

\[ i_L = 0 \quad (5) \]
\[ i_s = E_B/R_L \quad (6) \]

Mode D—Controlled rectifier on, flux is being set in the negative direction in the saturable reactor. It is assumed that the mutual impedance between the gate circuit and the load circuit in the controlled rectifier is negligible.

Kirchhoff’s voltage equations for the load and gate circuits are written for load:

\[ e_s = N_2 \frac{di_s}{dt} + R_d i_s \quad (7) \]

For gate:

\[ E_n = N_1 \frac{di_s}{dt} = R_s i_s \quad (8) \]

The required net ampere-turns in the saturable reactor in order to be in mode D operation

\[ N_{dL} - N_{d} = K \quad (9) \]
\[ i_s = N_{sL} - N_{s} = K/N_1 \quad (10) \]
\[ i_s - N_{dL} - E_B \quad (11) \]

From (7) and (11),

\[ i_s = N_2 \left( \frac{N_{sL} - K}{N_1} - E_B \right) + R_d i_s \quad (12) \]

From (10) and (12),

\[ i_s = N_2 \left( \frac{N_{sL} - K}{N_1} - E_B \right) + R_d i_s \quad (13) \]

Setting \( N_{dL}/N_1 = \eta \) and solving for \( i_s \),

\[ i_s = E_s \sin \omega t + \eta E_B + \eta R_s K/N_1 \quad (14) \]

Gate current during mode D operation is obtained by solving Eq. 7 and 8 and takes the form

\[ i_s = \frac{E_s + \eta E_B + \eta R_s K/N_1}{\eta R_s + R_L} \quad (15) \]

Time delay

\[ \Delta T = N_1 (\Delta \phi) \times 10^{-7}/E_B \quad (16) \]

where \( \phi = BA \)

The output current pulse is available every \( n \)th cycle of the supply frequency, where \( n \) can be made to vary from 1 to 10, and control is obtained by d-c excitation in the gate circuit. Gate circuit voltage versus output current repetition rate is illustrated in Fig. 2G. Figure 3 shows the output curves.

The diode in the output circuit is used to prevent thermal runaway in the controlled rectifier when the anode is going negative in respect to the cathode and there is a positive voltage from gate to cathode of the controlled rectifier.

Typical curves1 of instantaneous gate voltages versus instantaneous gate current for a controlled rectifier for various ambient temperatures are shown in Fig. 4.

tween the load circuit and the gate circuit during this period of time. This assumption can be made if the mutual impedance in the controlled rectifier is neglected and if the magnetic material has an ideal BH loop. Curves of the load current and gate current are illustrated in Fig. 2C. The time duration of mode C operation in Fig. 2C has been exaggerated for illustration purposes. In a practical timing circuit, mode C terminates at approximately 1/90 of a positive half cycle of the supply voltage.

Mode D operation will be completed when the net ampere-turns of the saturable reactor is equal to \(-H_{1s}/0.4\) sec. The value of \( H_s \) depends on the frequency of the load current.

Mode D begins when the saturable reactor is at point 4 on the BH loop. Equivalent circuits for the gate circuit and the load circuit are given in Fig. 2E. For this discussion the resistance of the anode to cathode and gate to cathode of the controlled rectifier are considered to be negligible compared to the other resistances in the circuits. Also, the mutual impedance between gate circuit and the load circuit in the control rectifier is neglected.

Assuming that the saturable reactor behaves like an ideal transformer, the volt-time area available for flux in the controlled rectifier is represented by \( V' \) in Fig. 2F. Equations for the load circuit and gate current are given in the design box.

The timing circuit of Fig. 1 was designed to operate at 400 cps. The output current pulse is available every \( n \)th cycle of the supply frequency, where \( n \) can be made to vary from 1 to 10, and control is obtained by d-c excitation in the gate circuit. Gate circuit voltage versus output current repetition rate is illustrated in Fig. 2G. Figure 3 shows the output curves.

The diode in the output circuit is used to prevent thermal runaway in the controlled rectifier when the anode is going negative in respect to the cathode and there is a positive voltage from gate to cathode of the controlled rectifier.

Typical curves1 of instantaneous gate voltages versus instantaneous gate current for a controlled rectifier for various ambient temperatures are shown in Fig. 4.

Novel Approach to Pulse Amplifier Design

Current to charge load and stray capacitances is supplied by auxiliary amplifier. Standby current is reduced, gain is improved

By J. F. GOLDING, Marconi Instruments Ltd., St. Albans, Herts, England

Linear amplification of a pulse waveform is, ideally, the reproduction in the load of all frequency components of the waveform correct in amplitude and phase. Conventional pulse amplifiers, therefore, normally keep the effective series resistance low compared with the shunt capacitive reactance for all wanted frequency components. This is usually achieved by reducing plate load resistance, by negative feedback, or by a limited use of inductive correction which effectively reduces the shunt capacitance at certain frequencies.

The amplifier described is suitable for the application of 50-volt pulses with rise time of the order of 0.1 µsec to capacitive loads of upwards of 100 pf. Its design is based upon the fact that the necessity for wide frequency bandwidth occurs only during the transient portions of the pulse—the leading and trailing edges.

The action of the pulse amplifier is more easily explained, however, by energy transfer rather than frequency response. For, in any pulse amplifier, limit to the steepness of output-pulse edges is imposed by shunt capacitance charging time. This charging time varies inversely with available current and, subject to limitations, current, in turn, is inversely proportional to source resistance.

Common methods of reducing source-impedance result in high plate current during the quiescent parts of the pulse waveform. If the conventional type of amplifier is to be used with positive and negative pulses, it must be operated in class A with the result that a high level of no-signal current is also drawn.

A numerical example will best illustrate this disadvantage of conventional pulse amplifiers. Regarding a pentode as a constant current generator, the rise-time of R-C coupled amplifiers is given by

\[ t = 2.3026 \times \frac{C}{R} \]

where \( C \) is load capacitance and \( R \) is load resistance, and \( t \) is time for the voltage to reach 90 percent of the pulse height. Thus if \( C = 100 \) picofarad, \( t = 0.1 \) microsecond, \( v = 50 \) volts, then \( R = \frac{10^3}{(2.3026 \times 100 \times 10^{-10})} \) ohms = 430 ohms. Plate resistance is therefore 430 ohms and plate current 50/430 = 0.116 ampere. To handle positive and negative going pulses, the tube must be operated in class A, implying a standby current of over 100 ma.

Furthermore, with plate load of 430 ohms and transconductance of, say, 10 mmhos, the gain would be only 4.6, as compared with 25 for the system to be described. A novel procedure is adopted in the following design, whereby an auxiliary amplifier is used to provide the short-duration charging current drawn by the shunt capacitance during the transient parts of the pulse. Thus, with the auxiliary amplifier supplying high-value charging currents, the main amplifier need provide only a comparatively small standby current in the plate load.

The basic arrangement of the system is shown in Fig. 1. Tube \( V_i \) is the main pulse amplifier. Total capacitance shunting its output is represented by capacitor \( C_s \), shown dotted. Current in the shunt capacitance is sampled by inserting a low value resistor in series with part of it. This is done by means of the network \( C \) and \( R \), where capacitance \( C \) actually forms part of the total shunt capacitance. Providing the time constant of this network is small compared with the rise time of the output pulse, the instantaneous voltage across \( R \) is

![FIG. 1](image-url)
directly proportional to the instantaneous current in the total shunt capacitance.

The differentiated voltage pulse developed across \( R \) is amplified and inverted by tube \( V_n \), and the output from the plate of this tube is fed to the grid of tube \( V_o \). Tube \( V \) is a class \( B \) amplifier connected in shunt with tube \( V_o \).

A sharp positive-going step voltage applied to the grid of tube \( V \) causes it to draw an increased current so that \( C_r \) and \( C_i \) begin to discharge. Pulse output voltage, however, does not increase to its peak until these capacitances have discharged fully. But, because of the amplified differentiated pulse appearing at its grid, tube \( V \) conducts heavily during the discharge period giving a steep transient edge to the output pulse.

It is important that the gain of the auxiliary amplifier comprising tubes \( V \) and \( V_o \) be just sufficient to supply the charging current for the shunt capacitance. If the gain is too small the rise of the pulse will be too slow and, if it is too large, the circuit will tend to oscillate.

In the completed amplifier the effective gain is finally set up empirically by a preset control; so a practical calculation of the required gain can be based upon the assumption that the time constant \( C_r \cdot R_i \) is negligible compared with the rise time of the output pulse.

It can be argued that the instantaneous current \( i_s \) in the shunt capacitance. If \( i_s \) is less than \( i_{es} \), part of the charging current will be drawn from tube \( V \); it will be flowing in \( C_r \) rather than \( R_i \) and the correct instantaneous voltage will not be developed. Conversely, if \( i_s \) is greater than \( i_{es} \), part of the current from \( V \) will flow in \( R_i \) causing the instantaneous voltage to rise above peak pulse height and producing instability.

The output from \( V_o \) is equal to the voltage developed across \( R \), multiplied by the combined transconductance of \( V_r \) and \( V_i \). Calling this transconductance \( A \), the relevant design formula becomes:

\[
A = (C_r + C_i) \cdot C_i R_i \quad (1)
\]

The rate of rise of the output pulse is limited by two primary factors, the ability of the auxiliary amplifier to deliver sufficient charging current and its ability to respond to the brief differentiated pulse developed across \( R \).

The output from \( V_r \) is equal to the voltage developed across \( R_r \), modified by the combined transconductance of \( V_r \) and \( V_i \). Calling this transconductance \( A \), the relevant design formula becomes:

\[
A = (C_r + C_i) \cdot C_i R_i \quad (1)
\]

The output from \( V_r \) is equal to the voltage developed across \( R \), multiplied by the combined transconductance of \( V_r \) and \( V_i \). Calling this transconductance \( A \), the relevant design formula becomes:

\[
A = (C_r + C_i) \cdot C_i R_i \quad (1)
\]

The rate of rise of the output pulse is limited by two primary factors, the ability of the auxiliary amplifier to deliver sufficient charging current and its ability to respond to the brief differentiated pulse developed across \( R \).

The first of these depends upon the maximum available instantaneous plate current from tube \( V \). The necessary current is readily calculable from the capacitance of the load plus the stray capacitance of the amplifier and the required pulse rise time. If it is assumed that the pulse has an exponential rise, the instantaneous current to charge the shunt capacitance is given by the expression:

\[
i_s = \frac{C_r V}{T} e^{-\frac{t}{T}}
\]

where \( i_s \) is the instantaneous charging current, \( V \) is the pulse height, \( T \) is the effective time constant.

The charging current is at its maximum at time \( t = 0 \) and is then equal to \( C_r V \). If the rise-time is reckoned as that required for the voltage to reach 90 percent of pulse height, \( T \) is given by the formula:

\[
T = \text{time of rise}/2.3026
\]

And the peak current required then becomes:

\[
i_{es} = 2.3026C_r V \cdot \text{time of rise} \quad (2)
\]

The rise time of the auxiliary amplifier is determined by the response of tube \( V \) as a voltage amplifier. For a mathematically perfect exponential rise to the output pulse the maximum current should be available at time \( t = 0 \). This implies an instantaneous response on the part of \( V \). However, rise time is normally reckoned as being the time elapsing between 10% and 90% of the voltage step; practical pulses are seldom truly exponential, having some rounding at the start of the rise.

Therefore, there is negligible deterioration if the rise time of the auxiliary amplifier is about a tenth of that of the desired output pulse.

The amplifier system described in this article is not intended for fast-rise pulses, although no tests or calculations have been made by the author to discover its ultimate limitations in this respect. As the rise time is reduced, however, it becomes difficult to obtain sufficient gain from \( V \) without using a large tube.

Obtaining sufficient output from \( V \), then depends upon the voltage...
developed across $R$. This, in turn, is determined by the ratio of $C$ to $C_\parallel$, and the value of $R$. The capacitance ratio is largely decided by the total amount of shunt capacitance that can be tolerated; the resistor value has a direct bearing on the stability of the system. For, if the time constant of the sampling network is too large, the potential developed across $R$ will correspond to the voltage across $C$, rather than the charging current.

From the mathematical analysis of the amplifier the following expression has been derived for the fastest rise obtainable without instability.

$$V' = 1 - \left[ 1 + \left( \frac{\sqrt{C_\parallel R}}{C_\parallel R} - 1 \right)^{-1} \right] \times \exp \left[ -\frac{1}{t} \left( C_\parallel R_{1/2} \right)^{1/2} \right]$$

where $v$ is the instantaneous output voltage, $V$ is the pulse height, and $t$ is the time. This expression assumes an ideal auxiliary amplifier.

The circuit in Fig. 1 provides for negligible deterioration of the positive-going edge of the output pulse, but it does not operate when the input voltage to the grid of $V_i$ is a negative-going step. The circuit of a complete amplifier suitable for positive-going and negative-going pulses is shown in Fig. 2.

Two additional tubes $V_i$ and $V_{ii}$ form a second auxiliary amplifier which provides the charging current for the shunt capacitance during the positive-going output step. The operation of tubes $V_i$ and $V_{ii}$ is similar to that of $V_i$ and $V_{ii}$, respectively. However, as this second pair of tubes operates in the reverse direction from the first pair, it is necessary to connect it between the output line and a separate 500 volt line.

The circuit shown in Fig. 2 is an experimental amplifier, designed to provide a 50 volt output pulse with rise time 0.1 $\mu$s across a capacitive load of about 100 $\mu$F. A 6AM6 tube (similar to 6AK5) is used in all stages.

The required maximum cathode current, obtained by substitution in expression (2), is 2.3026 x $10^{-10}$ x 50 x $10^2$ amps = 115 ma. The 6AM6 is capable of delivering about 300 ma instantaneous current so it is adequate for use as $V_i$ and $V_{ii}$.

With a 10,000 ohm plate-load resistor and a B+ voltage of 250 volts, tube $V_i$ has a dynamic $g_m$ of 2.5 mhos, giving a voltage gain of 25. The load capacitance having been arbitrarily set at 100 $\mu$F, 10 $\mu$F is chosen for capacitor $C$. The stray shunt capacitance is small compared with the load capacitance and, in this experimental circuit, may be neglected. To keep the time constant of the sampling network small compared with the rise time, the total for $R_i$ is made 500 ohms. This is shared between the two auxiliary amplifiers so that each responds to the voltage developed across about of each auxiliary amplifier must be twice that shown above, or 40 mhos. This figure is only about six times the $g_m$ of the tube used, so the voltage gain of $V_i$ and $V_{ii}$ need only be of the order of seven to allow for small circuit tolerances. This gain is easily achieved with the use of 1,500 ohm plate-load resistor. The stray capacitance shunting this resistor should not exceed 7.5 $\mu$F even allowing for wiring strays. This gives a time constant for the plate circuits of tubes $V_i$ and $V_{ii}$ of the order of 0.01 $\mu$s, so there will be negligible deterioration of the differentiated pulse if the rise time of 0.1 $\mu$s is adequate.

Because of component tolerances and other variations, it is not possible to set the gain of the auxiliary amplifier precisely; adjustment is made with variable resistors $R_i$ and $R_{ii}$. These resistors control the voltages applied to the respective auxiliary amplifiers; thus they control the effective gain of these circuits.

The amplifier is set up empirically. A pulse signal having a rise and fall time of less than 0.1 $\mu$s is fed to the grid of tube $V_i$. Output pulse is monitored by a cathode-ray oscilloscope. With the desired capacitive load connected, variable resistors $R_i$ and $R_{ii}$ are adjusted for the sharpest obtainable output pulse with no overshoot on the leading and trailing edges.

Figure 3 indicates the form of oscillograms of the output pulse for various settings of the variable controls. In the circuit arrangement of Fig. 2, the settings of the controls are interdependent so that it is necessary to adjust them simultaneously. Simultaneous adjustment can be avoided by wiring them as potentiometers rather than variable resistors, although this has the theoretical disadvantage that the time constant of the sampling network would be slightly higher.

The total mean plate current consumed by the amplifier is of the order of 15 ma.

ROBERT GAMERO
and DUKE WITHROW,
Coast Pro-Seal and Mfg. Co.,
Los Angeles, Calif.

CABLE SYSTEMS using cold-molding techniques have received considerable attention in the past few years. Cold-molding—with castable elastomers—uses a polymer in liquid form which cures to a solid elastomer from heat, a curing agent or both. The trend to the technique is extending to industrial areas.

EPOXY RESINS—Epoxy casting resins do not have rubber-like flexibility and are therefore not tabulated.

SILICONES—The so-called RTV silicones cure, by catalyst, to a rubber having excellent electrical performance, resistance to temperatures in excess of 500 F and good flexibility at low temperatures. Because of their high cost and mediocre physical characteristics, they are used only in cable systems designed for high temperatures and only then in conjunction with extruded silicone sleeving. Lack of suitable primers also presents obstacles to extensive application.

POLYSULFIDES—This class of liquid polymers represents almost the ultimate in ease of use and reproductive. However, they are characterized by extreme cold flow under moderate load deflections and only fair mechanical and electrical properties.

VINYL PLASTISOLS—This type of plastic holds a special position among cast-in-place polymers: it is cured by heat alone. When ground to a small particle size it is easily dissolved in a wide variety of plasticizers at temperatures of 300-400 F. Upon cooling, a plastic is formed with rubber-like properties. While the low cost of the plastisols is attractive and their performance is frequently satisfactory, they present many difficulties.

POLYURETHANES—Adaption of polyurethane liquid polymers for cable molding has become widespread in the past few years. While they are already replacing polysulfides and the plastisols it is not anticipated that the use of silicones will be affected.

PRIMERS—Because of the variety of substrates to which the molding compound must adhere, it has been typical to use primers. The problems of adhesion are compounded by sleeving and insulation materials. Manufacturers of extruded rubber products must meet specifications but do so with different compounding ingredients. For these reasons the suppliers of molding compounds have developed primers for chloroprene, vinyl, nylon, dacron, polyethylene, and conductor metals.

electronics • MAY 6, 1960
A telemetry transmitter for a late-model satellite incorporates the novel phase modulator circuit to be described. This circuit developed from an NASA requirement to investigate further the Van Allen radiation belt from a satellite in a high-apogee orbit with a life expectancy of 12 to 18 months. The transmitter, which has an output of 300 mw, operates on a frequency of 108.03 Mc.

A primary requirement for this satellite transmitter was that it be disk-shaped. Further, for easy servicing, the sections of the transmitter were constructed in pie-slice modules around the disk (see photo); modules are individually potted in foam. Direct-current power to the modules is supplied near the center of the disk; r-f signal terminations are near the outside of the disk for isolation.

Complete circuit for the transmitter is shown in Fig. 1. The crystal-controlled oscillator circuit uses a feedback network which excludes the crystal to prevent the oscillator drop-out effect with tuning. Its output is approximately 2 mw at 100 ohms.

The driver takes 2 mw input and furnishes an output of 39 mw matched to 50 ohms by the pi-network. By tying the collector to ground for a heat sink the transistor output must be taken from a point common to the emitter and base. The power amplifier is similar to the driver except that a balun transformer is used to convert the unbalanced input to the balanced condition required by the emitter and base of the transistor. Transistor output power is excluded from the previous circuit by the high impedance of the balun.

The telemetry amplifier is required for gain and preemphasizing the subcarrier signals.

The phase modulator circuit (see Fig. 1) is a modified conventional bridged T network evolved from a lattice network. Its advantages, besides simplicity, are: a modulating capability of ± 1.5 radians with a minimum audio signal in the frequency range of 400-1,300 cps; more favorable operating parameters; greater suitability to low impedance characteristics of the crystal oscillator output circuit.

Figure 2A shows the basic lattice network that can be evolved into a bridged T. If the legs are reactive and reciprocal with respect to the characteristic impedance, then the network has zero attenuation to all frequencies and a phase shift that changes with frequency. For a phase modulator it is desired rather that the phase shift at the constant input frequency be variable. This can be done by varying the two reactive legs together so that the reciprocal relationship is maintained. One pair of reactive legs may be capacitive diodes; then, to be reciprocal, the other pair of legs must be inductances which can be varied electronically. This problem may be solved by quarter-wave networks which have the same characteristic impedance as the lattice, because when a quarter-wave network is terminated with a reactance, the reciprocal to this reactance is always seen at the other end of the quarter-wave network. Therefore, the evolution to Fig. 2B allows the exclusive use of identical capacitance diodes as the \( jX \) reactances. To reduce the diodes required to two, the hybrid version shown in Fig. 2C or the bridged transformer \( T \) of Fig. 2D may be used. Either is classically equivalent to Fig. 2B. The \( T \) gives a common input and output terminal with the simplest transformer. The variable reactance, \( j2X \), of Fig. 2D may be a capacitance diode alone or it may be the diode combined with other reactances. The tangent
Transmitter FOR RADIATION SATELLITE

novel phase modulator circuit based on a modification of conventional bridged-T network

function of the basic phase formula (Fig. 2A) and the capacitance-voltage characteristic of the capacitance diode are two nonlinearities to be considered when trying to obtain a linear relation between diode control voltage and phase shift in the modulator. By forming the basic reactance, \( jX \), from a capacitance diode and linear inductance in series or shunt it is possible to find combinations where the two nonlinearities compensate. The shunt combination results in less signal voltage on the diode. For most capacitance diodes: \( C = C_0 / \sqrt{E_n} \), where \( C \) is capacity, \( C_0 \) normalized capacitance at fixed bias, and \( E_n \) is the instantaneous voltage normalized with respect to the fixed bias. With diode and inductance in shunt

\[
1/\omega L = 1/(\omega C_0 / \sqrt{E_n}) - 1/\omega L
\]

Let

\[
\omega^2 = 1/\omega L \quad \text{and} \quad \omega X = \omega C_0 [\{1/\sqrt{E_n} - 1\}] = \{1/\omega L \} [\{1/\sqrt{E_n} - 1\}]
\]

By plotting this last equation it was determined that, by making \( X / Z_0 = 1 \), a linear phase versus diode control voltage characteristic could be obtained over a 1.5 radian shift in phase. A characteristic impedance of 100 ohms was chosen since at 50 ohms the diode capacitance required was large and stray inductances were troublesome. The phase modulator circuit in Fig. 1 may be seen to be similar to Fig. 2D. The upper \( j2X \) basic reactance is composed of \( CR_1 \) and \( T_1 \). The quarter-wave network is composed of \( C_0 \), \( L_0 \) and \( C_2 \). The second diode \( CR_2 \) has no inductance shunting it because a series capacitance at the input of a quarter wave network is equivalent to a shunt inductance at the network output, and therefore \( C_0 \) may be slightly reduced in capacitance to offset the equivalent inductance shunting \( CR_1 \). The mutual inductance of \( T_1 \) also provides the transformer action required in Fig. 2D and \( C_0 \) allows for slight differences in diodes and coils. \( C_1 \) and \( C_2 \) are blocking capacitors so that bias may be applied to \( CR_1 \) without upsetting the transformer \( T_1 \) symmetry. \( L_0 \) and \( L_1 \) are for application of bias and modulating signal to the diodes. \( C_0 \) and \( L_1 \) form a network to match the 100 ohm characteristic impedance to the 50 ohm module output terminals.
Frequency scanning is one technique of steering antenna beams electronically which has not found much use in airborne installations despite the obvious advantages of small volume and no moving parts. While frequency-scanned two-dimensional arrays will not necessarily replace more conventional reflector-type antennas, they do show considerable promise for high-speed vehicle applications.

Electronic beam scanning or sweeping can be accomplished by amplitude or phase control of an antenna-array aperture distribution. Amplitude scanning is obtained by keeping the phase distribution constant while varying the amplitude distribution of the individual radiators. Phase scanning is accomplished by varying the phase while holding the amplitude distribution constant. Of the two, phase scanning is the most common; frequency scanning is one method of phase scanning.

Frequency scanning can be understood by considering an array with a series feed involving several feed-line wavelengths between uniformly-spaced feed points. (An example is a snake or helical-waveguide feed.) For one frequency, \( f_a \), there is an integral number of delay wavelengths between feed points, and the radiating elements will be in phase and the beam will be broadside, Fig. 1A. When the frequency is less than \( f_a \), there will be a uniformly progressive phase lead all along the aperture and the beam will be directed away from broadside toward the feed. Conversely, when the frequency is greater than \( f_a \), there will be a uniformly progressive phase lag and the beam will be directed toward the load end of the array. Thus, as the frequency is swept from \( f_a \) to \( f_a \), the beam will scan from \(-\theta_0\) to \(\theta_0\).

As a working guide in the development of the ground-mapping antenna, a number of tentative specifications and design objectives were established. The more relevant of these are listed in Table I under Objectives.

Although the objectives might apply to any ground-mapping antenna, there is one characteristic of a frequency-scanned ground-mapping antenna which differentiates it from mechanically-scanned antennas. As is true of all electronically-scanned arrays, the frequency-scanned antenna beam lies on a conical surface, resulting in a

**Fig. 1** — As the frequency of the signal to the array is changed, the direction of the radiated beam is varied (A). Method for determining the angle of the radiated beam (B); scan pattern of 20-turn helical waveguide feed (C); wave paths in closed and grid-covered waveguides (D)
By controlling the driving frequency of an array, the transmitted beam can be controlled accurately. A slotted aperture array and a leaky grid array prove the feasibility of this method.

hyperbolic ground intercept as the beam scans off the normal to the array. This characteristic is best shown in Fig. 2, where three beam positions are indicated with their corresponding frequencies.

The prototype antenna is a two-dimensional array of waveguide radiators which are fed from a waveguide helical delay line. The aperture distribution required for the narrow azimuth beam is formed from 20 two-slot directional couplers which couple energy from each turn of the helical feed to the radiators. Two approaches were made in the development of the shaped-beam radiators and these resulted in two slightly different versions of the antenna. One version uses vertically polarized narrow-wall slot radiators with cross-polarization suppressing baffles; the other version exploits horizontally-polarized, leaky-grid radiators. The helical feed and both types of radiators are excited by a traveling wave.

The WR-51 size waveguide delay-line feed was made in the form of an H-plane bend helix to obtain the high degree of accuracy possible on a thread-cutting machine and for coupling convenience. A mean circumference of six guide wavelengths was used to obtain radiation normal to the array at 16.5 GHz. Scan across the ground was ±45 degrees, with end frequencies of 16 and 17 GHz. To excite the branch-line radiators, two-slot narrow-wall directional couplers were precisely aligned on each turn of the helix. Directional couplers easily provide the desired broadband coupling with good interelement isolation and impedance match. Like the helical feed, the coupler manifold was machine cut for accuracy.

Data for the two-slot directional couplers were measured on a test coupler with replaceable coupling-slot inserts. The range of coupling values was determined by the choice of a 30-db Taylor distribution, the number of helix turns, and the percentage of power to the load. For the 20-turn helix, coupling values ranged from 8.5 to 23 db down. Patterns measured on the helical feed to demonstrate scan are shown in Fig. 1C; scan angle is very nearly a linear function of frequency shift.

Both the shaped-beam radiator designs in Fig. 3 are based on the synthesis procedures outlined by A. S. Dunbar in his work on progressive-phased antennas for shaped beams. Using the principle of stationary phase, the procedures take a given amplitude distribution and determine a corresponding phase distribution to obtain a stated far-field pattern. Because of different practical design considerations in the two types of radiators, the manner in which the synthesis is applied varies. These differences are roughly analogous to the convergent-ray diagram and divergent-ray diagram shaped-beam reflectors.

Waveguide narrow-wall inclined
shunt slot arrays are widely used in large aperture antenna designs. In such antennas, slot spacings near one-half guide wavelength, \( \lambda_g \), are usually used to obtain approximately broadside radiation. If, however, slot spacings between 0.25\( \lambda_g \), and 0.45\( \lambda_g \), are used, the full range of squint angles required for the geometrical optics approximations obtained from the shaped beam synthesis can be obtained. It should be pointed out that backward-wave radiation (toward the generator) obtained with less than one-half guide wavelength spacings is used because of the practical considerations of slot density and freedom from multilobed responses.

Progressive slot positions in an element, such as shown in the array of Fig. 4, are established in a shaped-beam design by referring to the squint-angle data from the synthesis and a curve of squint angle versus slot spacing, considering each succeeding in-phase slot as a slot pair with the preceding slot. Corresponding slot conductance values are found by using the slot amplitude values derived for the synthesis and the computation procedure required for a matched traveling-wave slot array.

Since published slot-conductance to slot-inclination-angle data were unusable at other than approximately half-wavelength slot spacings—because of mutual coupling effects—new measurements were necessary. A family of WR-51 waveguide test sections, each containing ten equally-spaced slots, were fabricated to provide this data. Baffles required to suppress cross-polarized lobes were also built and used on the test sections to include their effect on slot conductance. Two different baffle openings were used to cover the range of slot spacings. Also, quarter-wavelength deep chokes were formed by the baffle construction, and dummy waveguides were clamped on either side of the test section during measurements.

Incremental slot-conductance values were determined by the insertion-loss method, assuming each of the ten slots to have the same conductance value. Families of slot-conductance to slot-angle curves were plotted which showed that

**Beam Shaping**

For a ground-mapping or ground-scanning radar system, it is desired that the output, such as a ppi presentation, be at approximately the same brightness and contrast over the whole area being scanned. The ground directly beneath the airplane should not appear so much brighter than the distant area that details or definition of some of the area is lost. The most practical way to obtain equal definition over the total area being scanned is to make sure that the signal received back at the antenna, after reflection from equal targets, is the same strength regardless of the distance traversed.

Investigations into the geometry of the problem and the radar range equation reveal that the power output of the scanning antenna, for a ground-mapping airplane, should be

\[ P = \text{csc}^2 \theta \cos \theta \]

where \( \theta \) is the angle between the horizon and the depression of the scanning beam. The curves below are taken from "Microwave Antenna Theory and Design" edited by Samuel Silver, Volume 12 of MIT Radiation Lab Series, McGraw-Hill Book Co., Inc., 1949.
conductance increases with slot spacing and baffle opening as well as slot angle.

A typical pattern measured on the eight-wavelength-long shaped-beam slot array (Fig. 4) is given in Fig. 5A. Data from this and other measurements over the 16-to 17-Gc band are included in Table I.

Excellent impedance characteristics resulted from the traveling-wave feed and the non-uniform slot spacing. The variation in radiation efficiency at the ends of the band caused a gain decrease of about 0.65 db at the extremities of scan.

The grid radiator arrays consist of rectangular waveguides with one narrow wall replaced by a flat wire grid and the other wall shaped so that the width dimension varies with distance along the guide. The grid is photoetched from copper-clad dielectric which serves as grid support and pressure seal. The shaped wall is machined into a metal slab which is grooved to hold the top and bottom wave-guide walls.

Operation of the grid radiators may best be explained in terms of ordinary waveguide operation. The TEo mode in a rectangular waveguide may be considered to consist of uniform plane waves bouncing between the side walls at such an angle that interference between them causes a zero electric field at the walls (see Fig. 1D). The angle, θ, of the bounce depends on the width of the waveguide and the frequency; when the width of the guide is just one-half wavelength, θ is zero; when the wavelength becomes very small with respect to the width, θ approaches 90 deg. and the waves do not tend to bounce at all.

Suppose one narrow wall is replaced by a grid of flat wires which are in line with the electric field. The resulting mode may still be considered to consist of plane waves bouncing between the grid and the opposite wall, except that some of the energy directed toward the grid passes on through space outside the grid. The remainder bounces back, as before, to continue a net movement of energy down the guide. Size and spacing of the wires determines how much is bounced; the angle at which the plane waves bounce is still dependent on the width of the guide, the wavelength, and the amount of interference which is necessary for the field to be zero on the solid wall. Since the energy that passes through the grid continues in the bounce direction, it may be seen that the angle of radiation from the grid-array element as well as the amplitude may be controlled by controlling the wire size and spacing simultaneously with the waveguide width.

The elevation pattern of such an array element 6.25 inches long at 16.5 Gc, with 10-percent power into the load, is shown in Fig. 5B. The patterns show a beam shape which is preserved with changes in frequency, but exhibits a tendency to scan. The undesirable beam scanning may be compensated by tilting the array. Assuming an antenna tilt is used, the performance data shown in Table I applies.

One of the problems with frequency-scanned antennas is providing beam-angle data takeoff. The problem was solved with the circuit shown in Fig. 1B. Directional couplers at each end of the helical delay line provide inputs to a phase detector. By virtue of the long electrical length of the helical delay line, the phase detector output will be amplitude modulated at an audio rate as the transmitter frequency is varied to achieve antenna beam scanning. After boxcarring and amplification, the audio frequency component can be used to drive a servo follower if a constant scan rate is used. In cases where intermittent and variable scans are required, a two-phase phase detector will provide continuous servo tracking under all scan conditions.

Use of directional couplers and traveling-wave elements necessitates the use of a large number of termination loads in the frequency-scanned antenna. To minimize the space required, 0.25-inch long resonant loads of epoxy-iron and carborundum-ceramic materials were used, giving vswr of less than 1.2 to 1 over the band.

The authors wish to thank J. K. Smith for his contributions to the angle takeoff circuit and resonant loads.

REFERENCES

FIG. 5—Pattern of 8-wavelength long, inclined slot element with baffles, at 16.5 Gc (A). Pattern of 6.25 inch grid element with 10 percent power in the load, at 16.5 Gc (B)
A simple battery-powered scaler has been designed for quantitative measurements in field radioactive-tracer studies. The instrument incorporates a binary scaling circuit driving a mechanical register, a pulse-amplifying circuit and a regulated high-voltage supply for Geiger-Müller tube operation. The transistor scaling stages are non-saturating and temperature compensated. Neon indicator lamps are used.

The instrument consists of a scale-of-64 scaling circuit driving a 4-digit mechanical register, a regulated high-voltage supply and a pulse amplifier. Timing is done with an ordinary stop watch. Power for the unit is furnished by 9 single cells, either flashlight cells or mercury cells, and a single 90-volt battery which supplies power for the neon indicator lamps. One set of batteries will permit operation for several months with an average use
Powered Portable Scaler

with frills to improve reliability and to reduce cost and weight

of 3 to 4 hours daily. Total weight of the instrument is 14\frac{1}{2} pounds.

The six transistor binary scaling stages are diode clamped for nonsaturated operation. Nonsaturated operation of the scaling stages was chosen for several reasons. The decrease in required triggering voltage allows operation from slightly lower supply voltages. Stability under extremes of temperature is improved, and the variation in current demand with attendant poor voltage regulation is reduced.

The circuit for a single scaling stage is shown in Fig. 1A. Readout for the stage is a commercial transistorized neon indicator. The power consumption of 0.5 mA from the 90-volt battery, and about the same from the bias supply (2.6 volts), is not excessive. A one-shot multivibrator is used to drive the first scaling stage. Provision is made for both high and low impedance inputs. The low impedance input drives the multivibrator directly. The high impedance input is through an impedance-matching stage and the high-voltage coupling network for the Geiger tube. The circuit of the input stages is shown in Fig. 1B.

The mechanical register used with the instrument is a 4-digit, reset-type electric counter with a 6-volt coil. Its maximum driving rate of 600 counts per minute determines the maximum scaling speed of the instrument. This, however, corresponds to a maximum scaling rate with a scale-of-64 circuit of nearly 40,000 counts per minute—well beyond the useful scaling frequency of most Geiger tubes.

The coil of the register acts as the collector load of a complementary multivibrator circuit, whose time constants are chosen to provide a 40-millisecond square-wave pulse across the register coil. The circuit is shown in Fig. 1C. Use of a power transistor as the second transistor in the circuit reduces the ON period resistance to a fraction of an ohm and provides reliable operation. A thermistor in series with the bias supply for the pnp transistor stabilizes operation of the circuit over a wide temperature range.

High-voltage power supply is a conventional blocking-oscillator circuit which supplies voltage either variable or regulated at 900, 1,000 or 1,100 volts. A 20-microampere movement meters the supply without excessive current drain. Regulation is accomplished by switching one of three corona-discharge tubes into the stabilizing circuit. At the same time the resistance in the oscillator bias circuit is changed to permit the proper regulation current through the regulator tubes. The supply circuit is shown in Fig. 1D.

The single-cell batteries are mounted for easy replacement, in clip holders just inside the back cover of the instrument. The 90-volt battery is mounted similarly. Because of the complexity of the battery connections, a 3-pole ON-OFF switch is provided. Pilot lights are used to indicate main power ON, high voltage ON and counting. While they introduce additional battery drain, these lights are desirable to lessen the possibility of leaving the instrument inadvertently turned ON.

The thermistor temperature-compensating element was added to the register-drive circuit as a result of the relatively wide range of operating temperatures encountered (50 to 110°F). No other operational difficulties were encountered.
Determining Radar Visibility

By NATHAN SLAWSBY,
Senior Engineer, Electronics Research Laboratories,

EFFECTIVENESS of a radar in the presence of jamming is usually measured in terms of its self-screening range. To define this quantity, consider the case of an aircraft with a white-noise jammer aboard flying a straight-line course which takes it directly over a surveillance radar. Generally, the transmitted power of the radar is much higher than that of the jammer. At sufficiently short ranges, therefore, the echo received from the target at the radar antenna is greater than the signal produced by the jammer, and the target is clearly visible to the radar operator. However, the radar echo decreases in strength as the fourth power of the range and the jamming signal falls off only as the square. As the aircraft moves away from the radar, the advantage shifts from the radar to the jammer. At sufficiently great ranges, it is impossible for the radar operator to distinguish the target in the jammer noise. As the range increases, the probability of detection decreases from nearly unity to nearly zero.

At some intermediate range, the detection probability must be exactly 50 percent. This range is defined as the self-screening range, the range at which the radar and the jammer are evenly matched. Thus, a large self-screening range indicates that the effectiveness of a radar is not seriously impaired by a jammer.

The equation for the self-screening range, \( R_s \), is

\[
R_s = \left( \frac{P_r G_r}{4 \pi P_j G_j} \right)^{1/2}
\]

(1)

Table I defines terms used in this and other equations.

Another quantity of interest is termed the screening range. Consider a situation in which a jammer carried in one aircraft attempts to prevent the radar from detecting another aircraft. In this case, the jammer generally radiates into a side-lobe of the radar radiation pattern at the time the main-lobe radiation illuminates the target. The screening range, \( R_s \), which is the range at which radar and jammer are equally matched in this situation, is given by

\[
R_s = \left( \frac{P_r G_r R_i^2}{4 \pi P_j G_j} \right)^{1/2}
\]

(2)

In both of these equations, the visibility factor \( V \) is the one term which may not be readily determined. Visibility factor can be determined from Fig. 1 if the false alarm rate which the radar operator can just barely tolerate is known.

The requirement of 50-percent detection probability does not completely specify the visibility factor. It is also necessary to state the rate at which noise spikes can be allowed to exceed the detection threshold of the radar and generate spurious targets. Since the visibility factor is used to determine the range at which neither the radar nor the jammer has a clear advantage, this rate must be high enough to cause some distraction to the radar operator without confusing him completely.

The detection threshold is arbitrarily set to yield one false alarm per beamwidth in the self-screening case and one false alarm per scan in general screening case. The rates differ because in the self-screening case, the jammer is in the main lobe at the same time as the target, while in the general case, the jammer radiates into a side lobe.

The false-alarm probabilities are determined by

\[
\begin{align*}
P_a &= \frac{1}{10.74 R_s} \\
P_s &= \frac{n f_r}{645 R_s f_s}
\end{align*}
\]

These equations assume that the radar display may be subdivided into a number of data positions with dimensions corresponding to the duration of the transmitted pulse and the half-power beamwidth of the antenna. \( P_a \) is the reciprocal of the number of these data positions in a

silicon
diodes

Advance-engineered diffusion techniques are now applied to CBS silicon diodes. Fast switching . . . high conductance . . . high temperatures . . . high voltage . . . low capacitance . . . and low reverse current are achieved.

The diffusion technique offers many other advantages over the alloying method: Close process control of all parameters, great uniformity, and high reverse voltage for a given resistivity through the graded junction. Hermetic sealing of miniature glass package also contributes to the exceptional life.

Now you can have proven CBS reliability in diffused silicon diodes. Watch for further announcements on this growing CBS silicon line.

Note the two major classifications particularly designed for computers in missiles, rockets, airborne and industrial equipment. Typical applications include switching, pulse, flip-flop, modulator, demodulator, discriminator, clamping, gating and detector circuits. Write for complete technical Bulletins E-373 and E-374.

beamwidth; and \( P_n \), that of the number in a complete scan.

The number of hits per scan, which, for a point target, is equal to the number of pulses per beamwidth, is given by:

\[
n = f_s \theta_s / 6 f_s
\]

Use of Fig. 1 will be illustrated by finding the \( R_s \) of a target with a 1 sq-m mean cross-sectional area, screened by a jammer which has these characteristics: \( P_j = 1 \text{ w/m}^2 \), \( G_j = 2 \), \( R_s = 1.61 \times 10^6 \text{ m} \).

The radar has these characteristics: \( \theta_s = 3 \text{ deg}, f_s = 8 \text{ rpm}, f_r = 400 \text{ pps}, \tau = 2 \mu \text{sec}, R_s = 200 \text{ miles}, G = 316, K = 3.16 \times 10^6 \text{ Kc}, P = 1 \text{ Mw} \).

Solving for hits/scan, \( n = 400 \times 3/6 \times 8 = 25 \).

Calculating the false-alarm probability,

\[
P_f = 25 \times 2 \times 8 / 645 \times 200 \times 400 = 7.76 \times 10^{-4}
\]

From the chart, visibility factor is 1.15.

Inserting \( V \) into the screening-range equation,

\[
R_s = \left[ \frac{(1 \times 10^2)(316)(1)(2.6 \times 10^9)}{(12.6)(1)(2)(3.16 \times 10^6)(0.6)(1.15)} \right]^{1/4}
\]

Thus, \( R_s = 1.11 \times 10^6 \text{ meters} \).

Since the jamming signal is random noise, the method of computing visibility factor for various false-alarm probabilities and hits/scan involves the statistical nature of the detection process.

The envelope of a white-noise signal conforms to a Rayleigh probability distribution, given by

\[
P(R_x) \, dr = \frac{2}{K^2} R_x \exp(-R_x^2/K^2) \, dr
\]

That is, this expression shows the probability that the signal-plus-noise envelope exceeds any level of signal plus noise, \( r \). Here \( I_2(\epsilon) = I_1(\epsilon \times 
\]

To find the signal-to-noise ratio needed to give 50-percent detection probability for any false-alarm rate at one hit per scan, the noise distribution function is used to determine the threshold voltage which corresponds to that false-alarm rate. The required signal-to-noise ratio is that which yields a mean value which is the same as this threshold level. This is found by applying the series approximations for the signal-plus-noise distribution function.

The effect of integrating several hits per scan can be determined by applying the central limit theorem to the above distributions. Application of the theorem produces approximations for the probability distributions. The approximations have been used to generate the family of curves in Fig. 1. Derivation of the curves is based upon an ideal radar, and does not include such effects as lack of discrimination by the operator, antenna scanning loss, and mismatch of the i-f bandwidth to the pulse duration. Such effects, if they exist, degrade visibility factor \( V \) to an extent determined only by computing the losses in each case.

References

The smooth, easy insertion and extraction action, the self-wiping, self cleaning features and the double-sided, flexing action of both mating contact members make Micro-Ribbons the first miniature connectors to provide reduction in size with added reliability.

**CINCH MINIATURE BLUE RIBBON CONNECTORS**

Bodies are molded of an improved diallyl phthalate with extremely high impact strength and excellent dielectric features. Contacts are gold-plated over silver. Shells are cadmium-plated brass with clear chromate treatment. Receptacle shells have floating bushings allowing a float of .020 in each direction.

Miniature Capacitor Microphone

Dimensions of capacitor microphones have been reduced while retaining the desirable characteristics required for measurement applications and for use in TV and moving picture studios. A Mylar diaphragm 6 microns thick and 5 mm in diameter with gold deposited on it helped reduce size. The miniature microphone with 15-Kc bandwidth was described by C. Wansdronk of Philips Research Laboratories, Eindhoven, Netherlands.

Output of a capacitor microphone subjected to a given sound intensity is dependent on the ratio of change in capacitance to total capacitance. Total capacitance includes a parasitic capacitance that becomes proportionately greater as dimensions are decreased. Therefore change in capacitance should be made as large as possible by permitting as much diaphragm deflection as possible.

For omnidirectional capacitor microphones, deflection is about inversely proportional to stiffness, so stiffness should be as small as possible. However, bandwidth is limited at high frequencies by diaphragm resonant frequency, which in turn is dependent on diaphragm mass.

Decreasing diaphragm stiffness requires a decrease in diaphragm mass to maintain constant bandwidth. The Mylar diaphragm provided the reduced mass, but mass of surrounding air could no longer be neglected.

High-Frequency Detection

Smaller total capacitance increases internal impedance, resulting in increased preamplifier input impedance or a higher cut-off point for lower frequencies since microphone and preamplifier impedances form a high-pass filter. This problem can be overcome with high-frequency detection. A coil is inserted in series with microphone capacitance to lower impedance near resonant frequency and permit connection of the cable directly to the coil. Coil and microphone are mounted in a casing 5 cm long.

Varying impedance of the microphone-coil combination in Fig. 1A is compared to a fixed impedance. Zaalberg van Zeist proposed using the same elements in the fixed circuit, but the microphone was replaced by a capacitor.

Difference voltage contains only the side bands of the amplitude-modulated signal. The signal can then be amplified, mixed again with the carrier and detected. Low noise results, especially in silent periods. However, slight changes in the elements overload the circuit with carrier current. Also temperature changes between the two branches cause imbalance.

The fixed branch was replaced with a resistance (the resistance of the coil) to start with imbalance. The detector was inserted directly behind the transformer. A frequency was chosen in a straight part of the resonant curve not far from minimum to keep high S/N. Noise is mostly electrical and is probably caused by frequency and amplitude fluctuations of oscillator current. Measured constant noise level per octave was equivalent to sound pressure of 20 db/octave.

Directivity

To make the microphone directional, it is necessary to measure pressure gradient instead of absolute pressure. Sound is allowed to reach the diaphragm directly from the front and from the rear via holes in the side wall and in the fixed electrode.

In an equivalent electrical circuit, the side wall holes can be represented by an inductance and the cavity between the holes and the diaphragm by a capacitance. To a first approximation there is no phase difference between the holes and the rear of the diaphragm for frequencies below the combined resonant frequency of the holes and the cavity. Directivity characteristic is a figure of merit. To obtain a cardioid, an acoustical filter was built that changes phase proportional to frequency. This can be done with an RC or L/R low-pass filter.

If length l is an indirect path from the front to the side holes and c is sound velocity, RC = l/c or L/R = l/c. This relation must be fulfilled to get cardioid directivity. Effective detour l appeared as the distance between the front and the side-wall holes plus half the diaphragm diameter.

There is a problem with the frequency characteristic as well as the directivity characteristic at frequencies at which \( \omega (l/c) > 1 \). However, diffraction can largely compensate these problems. At lower frequencies where the electrical circuit forms a useful analogy, the cardioid shape becomes increasingly circular. As microphone diameter decreases, the frequencies at which this occurs are higher.

To control diaphragm resistance and obtain maximum effective capacitance, there is only the small slit between the fixed electrode and the diaphragm. From the theories of Crandall, this slit can be represented...
Like most circuit designers, you're probably often confronted with a wide choice of tubes which meet the electrical requirements specified by your design. But depending on other factors, such as the kind of environment in which the tubes are expected to operate, your choice may be limited.

Consider the Tung-Sol/Chatham 6080 tube family, for example. The 6080, the 6080WA, the 6080WB and the prototype 6AS7G all fit the same socket. The electrical ratings of these series regulator tubes are the same. Would you know which to specify for your power supply? The differences are vital. Knowing them can make all the difference in the ultimate reliability of your design.

If economy in original component cost is paramount and size is not a factor, then the 6AS7G may be your choice. If size is a factor, the smaller 6080 would be used. The 6080WA is the right tube if more closely controlled characteristics are important, if environmental conditions are severe, and if greater assurance of long life is needed. Where the tube is expected to operate under high ambient temperatures and severe vibration, and if many tubes are to be operated in parallel, then the 6080WB is best.

Of this you can be sure: Tung-Sol will recommend the "best" tube for your particular requirements. Once you have specified a Tung-Sol tube for your application, you'll be gratified by the superior performance and the highest operational reliability all Tung-Sol components provide.

Every Tung-Sol tube is the product of the highest manufacturing standards and unexcelled quality control.

Full technical details on the Tung-Sol/Chatham 6080 family are also available to you on request.

And if you would like prompt and able assistance in selecting the correct tube for your application, get in touch with Tung-Sol tube experts. They'll be glad to study your design and recommend the tubes best for you. Tung-Sol Electric Inc., Newark 4, N. J. TWX: NK193

He's discovered the cable that'll do the trick!

It's Hickory Brand Microphone Cable!

- EXTRA LIMP
- LONG FLEX LIFE
- LOW CAPACITANCE
- HIGH TENSILE STRENGTH

These plastic-insulated cables with non-marking jackets are lightweight, weatherproof and highly resistant to abrasion.

Use Hickory Brand Microphone Cables for all stage and studio work. Excellent for audience-participation programs. Use also for outdoor extensions.

All Hickory Brand Electronic Wires and Cables are quality-engineered and precision manufactured to meet the most exacting requirements.

SUPERIOR CABLE CORPORATION, Hickory, North Carolina

Corner Reflectors for Low Back Radiation

DESIGN analysis of corner reflector antennas has been carried out by the National Bureau of Standards under USAF sponsorship. Results provide comprehensive information on high-performance, economical corner reflectors.

Corner reflector antennas have two plane reflecting surfaces joined to form a corner. The driven element is placed in the aperture between the two planes. These antennas offer high gain, broad frequency response, narrow beam width and low back radiation.

Ionospheric scatter stimulated interest in corner reflectors. Despite earlier use, performance was known only qualitatively. The present investigation was to determine how gain varies with width and length of reflecting surfaces, aperture angle and driven element position.

The antenna investigated had two lattice-type wooden frames 12.3 ft wide (five wavelengths at 400 Mc) and 12.3 ft long supporting the reflecting surfaces. The reflectors...
were overlapping strips of aluminum fastened to the frames. Removal of one strip would subtract 0.2 wavelength from the surface. Width could be varied by trimming strip length. The frames were pivoted along the same axis, and aperture angle could be varied from 20 to 180 degrees.

The driven element was a folded half-wave dipole. Its position could be varied from 0.07 to 2.5 wavelength from the apex of the reflecting surfaces. The dipole support also served as a balun to transform system impedance to about 50 ohms. An exact match to a 50-ohm line was provided by a two-stub tuning unit. Gain was measured at 400 Mc.

Although collinear arrays of four or more dipoles are used in scatter antennas to obtain gains of over 20 db, performance can be predicted from that of a single dipole.

**Performance**

Minimum reflector width is 0.5 wavelength for the smallest usable gain. Increasing width to 2 wavelength increases gain. Greater widths produce little or no increase and may actually decrease it.

For maximum gain, the dipole must be at one of several positions from the apex. Exact position is a function of aperture angle.

With the dipole at the first position, gain increases monotonically as reflecting surface length increases. At the second or third positions, the same relation holds except for surface lengths less than 1.5 wavelengths. For the shorter lengths the relation is too irregular for simple analysis.

Maximum gain along the forward axis seems to be achieved with the dipole in the second position and the reflecting surface more than two wavelengths long and about two wavelengths wide.

Ionospheric scatter antennas for low vhf should have low secondary lobes and minimal back radiation to avoid interference from multipath propagation. The corner reflector can be designed to have very low back radiation. The small back radiation that does occur results from diffraction around the edges and penetration through small openings in the reflector surfaces.

**THE WORLD'S MOST VERSATILE OSCILLOSCOPES!**

with Plug-ins for All Needed Ranges . . .

All Needed Features . . . No Obsolescence.

**2- and 4-Channel Types**

Display multiple, high-speed signals without switching. From DC to 5 megacycle bandwidths.

Here is true multi-channel oscillography with features, performance, and prices "tailored" to your exact needs. Versatile plug-in pre-amplifiers, sweeps, and marker-calibrator circuits need be purchased only as you need them . . . when you need them. No worries of having "too much" scope now . . . not enough scope flexibility a few years later.

From simple one-channel monitoring jobs to difficult medical, biophysical and low-level strain gauge recording involving two, three or four channels, you'll find no jobs too small or few too large for these versatile ETC instruments.

Write for detailed specifications and prices.

PIONEERS IN MULTI-GUN C-R TUBES AND MULTI-CHANNEL OSCILLOGRAPHY.
Electronic Tube Base Potting

BY KENNETH L. ROHRER,
Electronic Tube Division,
Westinghouse Electric Corp., Elmira, New York

ELECTRON TUBE performance at environmental extremes is only as good as the foundation itself, the base material. A base should have high electrical resistance, high electrical strength, and high mechanical strength; it should be low in moisture absorption and resistant to high and low temperatures as well.

A number of base materials are satisfactory for potted tubes. For example, glazed ceramics and some conventional molded plastic base materials; nylon, diallyl phthalate, and nylontilled diallyl phthalate. Although not evaluated, orlon and polypropylene should have merit.

External leads of electronic tubes are protected by potting the volume surrounded by the molded base, glass stem, and glass exhaust tubulation. The potted resin completely surrounds the fragile, thin-walled tubulation through which the tube is exhausted and sealed.

When selecting and evaluating resins for base potting, the decision should be made to use either a flexible resin system or a system to match, as nearly as possible, the coefficient of thermal expansion of the glass. Typical coefficients of glasses used for electronic tube envelopes range from 46 x 10^-6 in/in/deg C to 89 x 10^-6 in/in deg C. The former corresponds to a hard glass; the latter relates to a soft glass. A wide mismatch of thermal expansions between glass and rigid plastics will cause glass breakage during temperature cycling.

Many natural and synthetic resinous materials have been evaluated to determine their suitability for base potting. They include epoxies and their modifications, epoxy-polyamide systems, castor-oil disocyanate resin mixtures, THIOKOL rubbers, silicone rubbers, and catalyzed tung-oil castor-oil mixtures.

Of all the flexible resin systems evaluated, RTV silicone rubber has been found to be most satisfactory. Supplied as a two-component system, RTV vulcanizes to a rubbery solid without pressure of temperature. In the cured state, it possesses unusually good electrical properties, resistance to moisture, and heat; it remains useful and flexible over a wide temperature range. Its published brittle point is about -100°F; the maximum serviceable temperature is 500°F.

RTV lacks one physical property which prevents it from being the ideal potting resin for bases—that is adherence to plastics. Fortunately, new and recent primers improve adherence to these surfaces. Properly applied, attempts to pull cured RTV from primed surfaces will cause cohesive failure in the rubber itself, leaving the rubber to primer and primer to base material bonds intact.

To obtain adherence to plastics, it is necessary to remove the glass and to roughen their surfaces before a primer is applied. Vapor blasting followed by degassing in trichlorethylene is a good preparatory procedure. In every failure, the primer peels away from the plastic surface and adheres only to the cured RTV. Published linear shrinkage values range from 0.2 to 1.1 percent after cure, depending upon the supplier.

Major deficiencies in most semi-flexible or flexible resins seem to be excessive moisture absorption and a severe increase in flexural modulus at extreme low temperatures. RTV is superior in both aspects.

Frequently, moisture absorption and flexural modulus of a given resin system seem to be closely related. A decrease unfortunately, in flexural modulus usually will increase a resin's ability to absorb moisture. Flexural modulus is inversely proportional to the amount of flexibilizer or modifier in a flexible resin system.

Inadequate adherence of RTV to unprimed plastic surfaces suggest two possible sources of trouble during service of potted tubes: penetration of moisture between non-adherent silicone rubber and the plastic base to form an electrical leakage path between the base pins; and shrinkage of the rubber away from the base walls to provide a very small air gap which may ionize at high voltages and high altitudes. On the contrary, however, experience has shown that the presence of such a gap during humidity cycling has presented no problem during electrical leakage tests or during altitude tests using applied voltages of 2,800 V at a pressure of 2 inches of mercury. Higher voltages and altitudes may require use of an RTV primer.

Although bases potted with silicone rubber without benefit of a primer to promote adhesion have passed humidity cycling, it was thought that additional deterrents to moisture penetration should be used. After potting, bases can be hermetically sealed by use of a lead-foil tape with a pressure sensitive backing. Its rate of transmission of moisture vapor is 0.10 g per 100 square inches per 24 hrs at 100°F. The tape is applied and formed to the outside diameter of both the plastic base and glass envelope, over the crevice between envelope and base. The W1-7198 makes use of such a tape. Finally, as an additional safeguard, the base, tape and glass area one-fourth of an inch above the tape are sprayed with a special epoxy-polyamide enamel designed to resist deformation and cracking between -65°C to 100°C and deterioration during humidity cycling.

Pressure filling methods have been found to be the most satisfactory for obtaining completely filled, voidless potted bases.

Inclusion of a magnetic shield in the design of the WL-7268 makes it necessary to pot, in addition to the base, the space between the metal shield and the glass envelope. Here the RTV cushions the glass envelope and shields against vibration during airborne operation. To facili-

Cross-sectional area of a potted base. The potted resin completely surrounds the fragile, thin-walled tubulation through which the tube is exhausted and sealed.

tate and speed the potting operation, and at the same time to provide a more resilient cushion, a thinned version of RTV is used. Thinned with 25 percent by weight of a high-dielectric silicone fluid, the cured resin shows no significant change in electrical properties and little change in other properties.

Ceramic-to-Metal Bonds

A number of methods of metallizing ceramics for brazing into ceramic-metal assemblies have been devised. According to L. W. Coughanour of the General Electric Power Tube Department, Palo Alto, California, the two most widely used are probably the molybdenum-manganese method developed by Nolte and Spurk, and the titanium hydride vacuum process of Bondley. Each method has its advantages, and each is capable of giving excellent results when properly applied.

Regardless of the method used, the formation of reliable, vacuum-tight ceramic-metal seals depends upon a number of factors. Among these are: a good bond formation between the ceramic and the metallizing material; proper design of the ceramic-metal subassembly, including the choice of ceramic and metal members to give the best thermal expansion match possible; and sound brazing techniques in forming the subassembly.

CERAMIC- METAL SEAL, the joint will normally be in compression. If the assembly is heated, however, the differential expansion of the ceramic and metal members may result in the generation of tensile stresses and shear stresses at the interface, with the tensile stresses being predominate. In a butt-type seal, shear stresses are more important on thermal cycling of the assembly.

Ceramic Circuit Boards

PRODUCTION of large ceramic pieces that serve as circuit boards could signify a major breakthrough in bringing the environmental specifications of printed circuits up to par with other electronic components. High alumina base and metal circuits of molybdenum and manganese can be subjected to temperatures in the 1,500° F to 2,000° F range. Mitronics, Inc., Hillsbide, N. J. feels that it has overcome the major obstacles in producing a ceramic printed circuit of respectable size. Their marketing efforts have been limited to select conversations with principal electronics manufacturers, and until more specific requirements are known, no general sales effort will be launched.

The company has just completed a six months investigation and development program which resulted in the production of ceramic bases for printed circuits that can be manufactured in mass production.

Shaping Tungsten

PURE TUNGSTEN can now be made into intricate shapes by special machining techniques. Parts can be fabricated to close tolerances with holes, threads, shoulders, tapers and other physical configurations. Melting point of this tungsten is over 3,000° C. It is finding use as inserts, nozzles, electrodes, bolts, screws and throats. Porous tungsten of controlled particle size and porosity can also be manufactured for filters and ion sources. Semicon of California, Inc., Watsonville, California is thought to be the only processors of this tungsten of the West Coast.
MANUALLY-OPERATED dielectric strength testers are hazardous to work with. The operator who places both hands on the tester risks high voltage grounding; consequently, 2 operators are needed. Also, human errors occur when instantaneous meter readings are taken and the controls manipulated.

To rectify these problems, an automatic control unit for such testers was developed. A single operator can safely and continuously make measurements over an extended period and while the components under test are operating in an environmental chamber. If plugs are used to disconnect the control unit, it can also be used for other applications requiring a variable voltage control over a fixed period of time.

Testing is automatic except for initial pretest settings. The operator sets the maximum voltage desired with the voltage arm (Figs. 1 and 2), which sets the high limit switch $S_1$. He then adjusts or inserts the time delay desired, switches on the high voltage with $S_1$ (circuit breaker), depresses the start switch, $S_2$, and observes the test to completion. $S_2$ is a stop switch.

To develop a dielectric strength tester that would have the needed capabilities, the following design objectives were established: low cost and portability; a high degree of accuracy, reliability and repeatability; immediate visual indication of test progress and failure warning; manual override of the automatic features, and elimination of physical contact between the operator and equipment after a test was started.

Low cost and portability were achieved by replacing the manual controls of an available tester with the automatic controls. The compact new unit attaches directly to the original cabinet.

The knob and scale were removed from the original tester's autotransformer. A calibrated dial disk, gear train, reversible motor, appropriate control stops and a readout indicating pointer were installed. The dial disk is calibrated to the same degree of accuracy as the voltmeter in the tester circuit.

The readout becomes more accurate because of expanded scales, one for d-c reading and the other for a-c reading. The smallest readable increment on the original scale was 200 v. With the expanded scales, readings of less than 50 v are accurately obtained. The motorized gear drive provides a constant test voltage buildup which is repeatable within 1 percent for successive tests. The voltage pointer indicates the maximum voltage obtained. Voltage is increased via the reversible motor.

Immediate visual indications of test progress and failure warning are given by the maximum voltage indicating arm and a high-voltage indicating light. The operator overrides the automatic features after the start of any test by using $S_2$. This switch immediately reverses

---

NOTEWORTHY FEATURES OF THE AMPEREX TYPE 7093
- Frequency Range: 34,512 - 35,208Mc.
- Power Output: 25KW
- Pulse Length: 0.02 microseconds
- Rise Time: 600KV per microsecond
- Weight: 4.2 lbs.
- Cathode: Philips dispenser-type
- Immediately available in production quantities.

BEFORE YOU BUY
PRECISION GEARS

Strict adherence to all A.G.M.A. specifications
All numbers of teeth available in aluminum and stainless steel
Consecutive tooth sizes in all pitches
Choice of four (4) bore sizes in flat gears at no cost
Tapes supplied at no cost on all precision gears
Blank configurations proportional to their diametral pitch
Gears "Mylar" sealed on trays to protect the precision

Quality Features

APPCO GEARS
Competitor A
Competitor B

APPCO Certified STOCK GEARS

OFFER ALL THESE FEATURES!

You get extra value in every APPCO Precision Gear. Extra value in the finest qualities not offered by other gear manufacturers. Compare them before you specify or buy!

Every APPCO Gear is made to A.G.M.A. specifications. Held to tolerances. Certified to precision-fit shaftings, and components. Each gear is sealed in plastic to be free of dirt, dust or corrosion and assure its arrival at your plant "factory-fresh" ready to use on the most critical assemblies.

APPCO Certified Precision Stock Gears are available in 32, 48, 64, 72, 96 and 120 diametral pitches of 14½° and 20° pressure angles. Spur gears, pin or clamp type...hubless and anti-backlash. For complete technical data and catalog write to...

ATLAS PRECISION PRODUCTS COMPANY
Division of Prudential Industries

the drive, thus returning the auto-
transformer to the zero position.

S. reverses the control disk if a
human error in the pretest settings
is detected. S. must be manually
turned to the off position during
any change to the apparatus or in
the settings. If breakdown of the
test component does not occur be-
fore required voltage is reached,
the test continues until the S. is
actuated, starting the time delay.

After the time delay, the drive
mechanism reverses, returning the
system to the starting point. If the
sample breaks down before the re-
quired voltage is reached, current
flows through the coil of RL., clos-
ing the contacts which actuate RL.,
This pulses RL. and releases the
mechanical hold on RL. This action
opens the power to the high voltage
section. When RL. pulses, it re-
verses the motor, causing the motor
to drive to the off position. If RL.
is inoperative, a slightly larger cur-
cent draw on a test-sample break-
down will cause the circuit breaker
coil to kick out, shutting off the
power to the high voltage section.

As a safety feature, the test
equipment interlock S., the cabinet
interlock S., and the door interlock

FIG. 2—Outline drawing of control
unit

MAY 6, 1960 • electronics
Closeup of control. Here, maximum voltage arm has contacted high limit switch.

S. were added. Power is shut off if the test equipment or cabinet interlocks are opened.

Another safety feature is the modification of the high voltage lead. Previously, the hot lead and ground lead were separate, resulting in high voltage leakage through the insulation of the lead. This shock hazard was eliminated by using a coaxial cable to make a self-contained grounded high voltage lead. High voltage is shielded to a few inches of the part tested.

The control may be inserted in the circuitry of any commercially available high-potential tester. RL. has been substituted for the connection between the circuit breaker and interlock switch of the tester. The only other change to the manual tester is the tie-in of RL. via an octal socket to the 115 volt, a-c line of the tester.

Protect Beryllium With Electroplate

METHOD of protectively coating beryllium metal is described in a patent (2,901,408) assigned the Atomic Energy Commission, by R. G. Townsend.

The steps in the process are: etching the metal in acid, briefly immersing the etched beryllium in a sodium zinicate solution, immersion in concentrated nitric acid, immersion in a second solution of sodium zinicate, electroplating a thin layer of copper over the beryllium, and finally electroplating a layer of chromium over the copper.

NEW SOLID STATE FREQUENCY STANDARDS
OUT-PERFORM MECHANICAL TYPES — COST NO MORE!

- New crystal controlled "L" models hold .025% to .005% tolerance at -55°C to +100°C, over 25 to 31 Vdc input, 5-2000 cps vibration at 15 g simultaneously.

- Qualified to MIL E-5272 C. Usable for airborne systems, facsimile, yet competitively priced with same-application mechanical types.

- Outputs up to 50 milliwatts, sine or square wave. Distortion, less than 10%. Weight, less than 4.5 ounces. Dimensions, 1 1/2" x 1 1/2" x 2 1/4".

Want to escape the price-versus-performance squeeze? Take your pick from a whole series of Model "L" Secondary Frequency Standards. These units are the first of their kind that offer space-saving design, improved performance and reliability without price penalty.

Send for engineering data. Write or telephone for prompt application assistance to Time Control Systems Division.
New On The Market

Tunnel Diode

LOW INDUCTANCE AND RESISTANCE

DEVELOPMENT of a technique for mounting a tunnel diode tab of triangular shape by the Philco Corp., Lansdale Division, Lansdale, Pa. has resulted in a diode with a series inductance of one millimicrohenry and a series resistance of one ohm.

Uniform peak current of one milliamper plus or minus 2.5 percent with most units within one percent has been achieved. Peak to valley current ratios are 5 to 1 and 10 to 1.

Typical performance shows peak voltage of 55 millivolts and valley voltage of 320 millivolts. The diodes have a capacitance of 5 microfarad while their negative resistance is 120 ohms.

Measured oscillation frequency is over 1,500 Mc. The units are packaged in a shortened, hermetically sealed transistor case with thin base and small alloy contact.

The tunnel diodes are available in prototype quantities at $10.00 each.

CIRCLE 301 ON READER SERVICE CARD

Magnetic Tape Plotter

FOR DIGITAL COMPUTERS

PLOTTING digital computer results on an x-y recorder is accomplished by a new plotting system developed by F. L. Moseley Co., 409 Fair Oaks Ave., Pasadena, Calif. The type 575 system includes digital tape transport, magnetic tape translator, tape control unit, record-playback amplifiers and an Autograf x-y recorder.

Subroutines for data and commands are recorded on tape at a computer tape speed of 75 or 112.5 in. a second. Tapes are played back at 3 in. a second for plotting.

The system's digital magnetic tape translator model 44 permits plotting continuous curves at up to 4 in. a second when these curves are generated by a computer interpolating routine where the points defining the curve are infinitesimally close together. When continuous curves are drawn, information changes 100 times a second.

In point plotting, the speed is 100 points a minute at 1 in. spacing.

Accuracy of the unit's digital-to-analog conversion is better than plus or minus 0.1 percent of full scale. The translator is completely transistorized and features illuminated visual display, automatic parity checking and automatic search mode.

CIRCLE 302 ON READER SERVICE CARD

Thermistors in Diode Cans

GOOD THERMAL CONTACT

GOOD THERMAL contact with sink surfaces is assured with disk thermistors packaged in diode cans. The thermistors are made by Fenwal Electronics, Inc., 51 Mellen St., Framingham, Mass.

The disks are available in resistance values from 5 to 11,000 ohms. Besides providing fast surface temperature sensing, the units can be mounted near transistors to compensate for their thermal limitations.

The thermistor mount can be electrically and thermally insulated from the mounting surface and provide easy mechanical attachment for other applications.

CIRCLE 303 ON READER SERVICE CARD

Miniature Varactor Diodes

UP TO 120,000 MC CUTOFF

MINIATURE pill varactor diodes for use in traveling-wave broadband parametric amplifiers at frequencies through X band are available in experimental quantities from Microwave Associates, Burlington, Mass. The diodes can be supplied with plus or minus 10 percent ca-
new system for flight safety

Uses Hughes TONOTRON tube to combine radar screen with pilot's field of view

Aptly called the "Magic Window," this new pilot display system developed by Autonetics Division of North American Aviation, presents any luminous pattern produced by a Hughes TONOTRON tube as an image painted in front of the pilot's normal view. Day or night, in any weather, the pilot can avoid obstacles, maintain attitude, safely accomplish difficult landings.

The grid shown is just one typical application. Any radar mode—terrain, fire control, weather, etc.—can be projected on the "Magic Window." In the ground mapping mode, the TONOTRON tube provides high fidelity reproduction of any desired information with high picture brightness and controllable persistence.

Hughes TONOTRON tubes are ideal for a wide range of applications including: Sector Scanning, "B" Scan Radar, Weather Radar Readout, Armament Control Radar, Plan Position Indicator information and Slow Scan TV.

TONOTRON tube models are available for your use in sizes of 3, 4, 5, 7, 10 and 21 inches—with electrostatic or electromagnetic deflection.

For detailed information and application data on TONOTRON tubes, write or wire: HUGHES, Vacuum Tube Products Division, 2020 Short Street, Oceanside, Calif. For export information, write: Hughes International, Culver City, Calif.
capacitance tolerance.
The firm is offering a series of five diodes with outside dimensions of 1" by 1" in. The units have minimum cutoff frequencies ranging from 30 to 120 Gc.
The pill varactors have ceramic to metal seals to insure ruggedness. The package shunt capacitance is approximately 0.2 μf. Series lead inductance is approximately 0.8 x 10⁻⁶ henry.
Stray susceptance is kept to a minimum by close tolerances maintained in fabrication. As a high-frequency harmonic generator, power outputs up to 20 milliwatts are reported in tripling X-band power to the 35 Gc region.
The diodes are being used as high-efficiency subharmonic generators in microwave computers. Other uses are as low-loss r-f switches in resonant cavities at microwave frequencies and for doppler radar sideband modulators through 16 Gc.

CIRCLE 304 ON READER SERVICE CARD

Electrostatic Storage Tube
2½-IN. DIAMETER; 9¼ IN. OVERALL
NARROW-BANDWIDTH video transmissions at radio frequencies, telephone line transmissions, equipment monitoring and freezing of transients are applications for a new small electrostatic storage tube developed by Allen B. Du Mont Laboratories, Inc., 750 Bloomfield Ave., Clifton, N. J.
The tube measures 2½ in. in diameter and 9¼ in. overall. It uses a conventional 14-pin base. The tube is designed for direct viewing.
Connections to the target assembly, collimator and screen are made through recessed contacts on the tube body. The tube uses two glass rodded guns.

The write gun is a high-current, high-velocity electrostatically focused and deflected type. The modulated beam writes information onto the storage target.
The view gun is a high-current, low-velocity type producing a flood of electrons that transfers stored information onto a storage screen for viewing.
Writing speed as high as 100,000 in. per second and a resolution of 50 lines per in. are attainable. Storage time is of the order of two minutes, erase time of 50 milliseconds and brightness level of 3,000 ft lamberts at 8 Kv.

CIRCLE 305 ON READER SERVICE CARD

Multiheaded Transistors
TWO OR MORE IN A CAN
Another approach to subminiatuizing transistor circuits is the use of multiheaded transistors. The units are being made by Electronic Transistors Corp., 9226 Hudson Blvd, North Bergen, N. J.
A multiheaded transistor combines two or more currently used types in the same can. This combination is said not to cause interference. The individual transistors have no contact with each other in the can.
Combinations of transistors include npn, pnp, audio, amplifier, computer, converter, general purpose, high frequency, low frequency, intermediate frequency, low noise, matched pair, medium frequency, mixer, oscillator, radio frequency, subminiature and switching.
The units are priced 25 percent less than the combined prices of the individual units.
The following types are immediately available in combinations of two in a JEDEC 30 package: 2N428 switching; 2N404 switching and computer; 2N48 audio; 2N302 high frequency; 2N482, 2N483 and 2N484 high-frequency entertainment types and 2N1372 and 2N1374 general purpose transistors.

Hughes S and X Band Parametric Amplifier Diodes

Hughes has designed parametric amplifier diodes that can give you noise levels of less than 2 db at X band using double sideband operation. In addition to low noise, these HUGHES® diodes also offer a number of other advantages. First, their high cutoff frequency means that you can obtain higher amplification and higher harmonic generation. Their ceramic package reduces stray capacitance and makes for more dependable performance levels.

With these characteristics, Hughes S and X Band Parametric Amplifier Diodes are ideally suited to the following applications: radar preamplifiers, frequency converters, phase shifters and harmonic and subharmonic generators.

For additional information, please write: Hughes, Semiconductor Division, Marketing Dept., Newport Beach, California. For export write: Hughes International, Culver City 5, California.
WHY YOU SHOULD
PROGRAM YOUR
TESTING
THIS BETTER WAY

WITH EECo's UNIQUE
80-BIT BI-DIRECTIONAL
PUNCHED TAPE PROGRAMMER

For automatic programming of
test equipment, the EECo TP-201A offers
these decisive advantages over stepping
switches or single-line 8-bit programmers:

(a) Far more elaborate programs can be automated...up to
240,000 bits per reel, presented at 80 bits per step. (b) Random
or sequential access to any of the 3000 frames on each 250-foot
tape. (c) Provision for visual selection of program step. (Printed
information on tape correlates with punched information).
(d) Reduced training time and skill requirements for tape punch
personnel. (e) Programs can be stored and re-used. (f) Small
size panel is 6"x11\(\frac{3}{4}\)", depth below panel 5\(\frac{3}{4}\)".

Tough Mylar tape contributes to improved reliability. No special
punch needed. Bi-directional electrical drive system. Positive
detent action for accurate positioning of tape.

Other models available for automatic programming, process con-
trol, and precision time base programming. Write for data sheet.

The Application of DATA PROCESSING TECHNIQUES

• • • to reduce man hours and increase production, in industrial and commercial operations, is a familiar problem to Anelex® Systems Division engineers.

This group has worked together for almost ten years, using digital techniques in the development of logical solutions to special problems of control, timing and data handling. They are also experienced in the development of specialized tracking, timing, communications and test systems for military applications.

Finished equipment required for these systems is produced by the Anelex manufacturing facility under direct supervision of the engineering group. This division is staffed by technicians and skilled craftsmen who have specialized in the production of unusual and sophisticated data processing equipment.

We will be glad to tell you frankly and promptly whether your particular requirement is within the capabilities of our Systems Division. Just write or telephone.

Oscillators
LOW DISTORTION

BURR-BROWN RESEARCH CORP., Box 6444, Tucson, Ariz. Transistorized, self-powered, and compact, the models 210 and 211 oscillators offer the user a reliable and isolated source of high purity sine waves. Line transients and ground loops are eliminated. Unusually low harmonic distortion is achieved by the use of high gain d-c operational amplifiers in a Wien bridge circuit. The d-c amplifier also permits tuning to very low frequencies.

D-C Amplifier
LOW-LEVEL

MAGNETIC RESEARCH CORP., 3160 W. El Segunda Blvd., Hawthorne, Calif., announces two new miniature low-level d-c signal amplifiers. Model 10-108-2 is designed to operate from 115 v 400 cycle power and model 12-105-0 is designed for 28 v d-c power. Both are ideally suited for temperature and strain measurements in industrial, military, and medical applications. Designed to accept an input signal in the mv range, the units produce an output signal ranging from 0 to 5 v d-c for use in telemetering, instrumentation and recording systems. Construction features reliable transformer type magnetic elements, which provide a high degree of isolation between the input and output.
New Processes Improve Instrument Sensitivity!

In delicately-precise instrumentation, parts must react to relatively small rotive forces. Here, bearing torque is the highly critical factor. Separator selection, bearing finish and clinically clean assembly areas are extremely important.

It's here that New Departure is setting new industry standards! Special dies and in-process gouging of separators assure ball retention with improved torque and vibration characteristics. In addition, new N.D. honing processes and Talyrond gauging deliver uniform accuracy to millionths of an inch. Moreover, having originated the first bearing industry "white room", followed by continuous experience, New Departure's present day, modern assembly areas approach fantastic levels of cleanliness.

An everyday example of N.D.'s contribution to improved instrument sensitivity can be found in the Smithsonian Institution-selected Micro Clocks. These vitally important instruments are accurately tracking both U.S. and foreign satellite movements in time determinations of 1 milli-second . . . and better!

For new performance and reliability in your precision instruments, ask your N.D. Miniature/Instrument Bearing Specialist to sit in on an early design level discussions. For further information call or write Department L.S., New Departure Division, General Motors Corp., Bristol, Conn.
Shown above are Huggins TWT's producing a power output range within ±1 DB over an input range of −40 to +5 DBM.

This pair of X-Band, light weight, PPM focused tubes is only one example of our ability to furnish TWT's to almost any specifications.

Trimmer Pot

ATOHM ELECTRONICS, 7648 San Fernando Road, Sun Valley, Calif. The W-51 subminiature trimmer potentiometer, for virtually all general purpose applications, has a standard range of resistance from 10 ohms through 100,000 ohms, with tolerance ±10 percent. These units, having 0.750 in. mounting hole centers, are available with 12 in. flexible insulated wire leads (W-51-F), solder lugs (W-51-L), and mounted printed circuit pins (W-51-P1).
For General Purpose DC Recording — Model 320

For recording two variables simultaneously, the Model 320 provides a versatile, transistorized amplifier for each input signal. The rugged 2-channel recorder assembly has heated stylus recording on two 50 mm wide rectangular coordinate channels, 4 pushbutton chart speeds, and 6 inches of visible chart. The Recorder can be placed vertically, horizontally or at a 20° angle.

MODEL 320 SPECIFICATIONS
Sensitivity: 0.5, 1, 2, 5, 10, 20 mv/mm and v/cm
Frequency Response: 3 db down at 125 cps, 10 mm peak-to-peak
Common Mode Voltage: = 500 volts max.
Common Mode Rejection: 140 db min. DC
Calibration: 10 mv internal = 15
Output Connectors for each channel accept external monitoring ’scope or meter
Price: $1495

NEW SANBORN PORTABLE DIRECT WRITING RECORDERS
FOR IN-PLANT, LABORATORY OR FIELD RECORDING

Two models of this 21 lb. brief case size recorder are available — Model 301 for AC strain gage recording, Model 299 for general purpose DC recording. Both provide immediately visible, inkless traces by heated stylus on 40 division rectangular coordinate charts... frequency response to 100 cps... 5 and 50 mm/see chart speeds... approx. 4 inches of record visible in top panel window.

MODEL 301 SPECIFICATIONS
The amplifier section of the Model 301 is an all-transistorized carrier type with phase sensitive demodulator. The power supply and internal oscillator circuits are also transistorized. Sensitivity: 10 uv rms/div (from transducer) Attenuator Ratios: 2, 5, 10, 20, 50, 100, 200 Carrier Frequency: 2400 cps internal Transducer Impedance: 100 ohms min. Calibration: 40 uv/volt of excitation Output Connector: for external monitoring ’scope or meter
Price: $750

MODEL 299 SPECIFICATIONS
Combines the dependability of transistors with the high input impedance of vacuum tubes for reliable broad-band DC recording. Sensitivity: 10, 20, 50, 100, 200, 500 mv/div and 1, 2, 5 and 10 v/div Input Resistance: 5 megohms balanced each side to ground Common Mode Voltage: = 2.5 volts max. at 10 mv/div sensitivity increasing to = 500 volts max. at other sensitivities Common Mode Rejection: 50:1 most sensitive range Calibration: 0.2 volt internal = 15 Output Connector: for external monitoring ’scope or meter
Price: Model 299 (with zero suppression) $700
Model 299A (without zero suppression) $650

AVON GEARS

- "Specific" for electronic equipment, control components, small tools, motors, and UNCOMPROMISING SPECS.
- Exacting tolerances held from commercial grade to ultra precision.
- Generated in wide range of steels, non-ferrous metals, and non-metallic materials.
- Capacity range: 12 to 200 d.p., and maximum O.D. of 7 1/2".

Make AVON Your "Gear Department"

Avon is completely tooled to follow your specifications precisely, and to produce the very best precision or commercial grade Fine Pitch gears for your specific needs. At Avon you can get one gear or a million of ALL types, ALL classes, from ALL materials.

Avon has a modern complement of the finest inspection equipment procurable... truly a setup tuned to the exacting tempo of the "Space Age." Your gear formula is followed with the utmost care. Result: Accurate assembly of your most critical units!

Avon's fifty years aggregate gear engineering experience guarantees an end product exactly as specified. We will be glad to work with you on any development project requiring Fine Pitch gearing... for either commercial or precision applications. You can depend on AVON. Send drawings or descriptions for free estimates.

World Radio History
AMPLIFIER NOISE

Accuracy is the basic objective in amplifier selection. When evaluating amplifiers for specific applications all errors must be considered. One such error, the noise level, determines the ultimate accuracy of the amplifier since the smallest observable signal cannot be less than the noise level. However, noise outside the frequency response range of the amplifier load can be filtered out or ignored with such read-out devices as galvanometer oscillographs.

Noise in an amplifier is any voltage component appearing at the output that has no counterpart in the input signal. Usually only the a-c component of the output is termed noise. The d-c component is called zero drift and its evaluation will be covered in another of this series.

Internally generated a-c components must be evaluated as to amplitude and frequency range. Noise may be divided into two general classes and measured as described below. (a) Random voltages of a broad band nature arising from thermal agitation in resistors and random tube or transistor noise... measurements on a peak-to-peak basis are often 10 times or more larger than the measured rms value over the same frequency band. (b) Narrow band voltages induced within the amplifier by line voltage or chopper excitation... these voltages are generally sinusoidal so that peak-to-peak values are only about 2.8 times larger than the measured rms values.

Testing amplifiers for noise

If the input signal is zero, any voltage components detected at the amplifier output can be identified as noise. A standard technique for measuring noise is shown.

The oscilloscope measures the peak-to-peak values, the VTVM in rms values. Equivalent input noise (eq. in) is the measured noise divided by the amplifier gain. For details write for Bulletin BE AN121.

Noise less than 0.03%

With a full scale input range of 30 mv, Honeywell's AccuData II Amplifier has a wide band (0-100 KC) noise specification of 8 µv (eq. in) and a peak-to-peak noise over a 0-10 cps band of 8 µv (eq. in) . . . less than 0.03% of full scale!

The AccuData II, a wide band differential input d-c amplifier with all transistor design, is especially useful for driving analog-to-digital converters, f-m magnetic tape systems and high speed oscillographs where low level signals such as thermocouple, strain gage and similar transducer outputs are to be accurately measured. Write for Bulletin BS DISA-1000 to Minneapolis-Honeywell, Boston Division, Dept. 7, 40 Life Street, Boston 35, Mass.

P-C Connectors
FOR 3/32 IN. BOARDS

Precision Connectors Inc., P. O. Box 96, Mineola, L. I., N. Y. Series 093 P-C connectors for 16 in. boards, feature Tri-Spring contacts, a new triple independent leaf spring action contact that firmly grips the p-c board over the entire contact area, assuring greater reliability, accepts maximum board tolerance variation with uniformly distributed contact pressure. Coined wiper spring provides positive redundant wiping action over entire contact surface, helper spring maintains uniform pressure over full length of contact, back spring insures contact wiping pressure immediately upon insertion of board. Scoring or other similar damage is eliminated. Contacts follow board displacement, prevent discontinuity caused by vibration or motion of the board. Contacts are self-aligning to residual warpage along the length of the board. Units are...

*REGULATED POWER MODULE

All design, development and production work has been completed for you in these RPM power modules. Buy them as catalog items, and get these advantages:

16 standard models—125 to 425 volts... 50 to 400 milliamps, plus 30 standard modifications with extended voltage and current ranges.

Excellent regulation—0.05% NL to FL, or 10% line change.

Compactness—RPM units are custom designed and built with our own transformers for most efficient use of space.

Super-rugged construction includes one-piece, cast aluminum housings and MIL hardware. RPM modules can be mounted in any position.

High reliability—achieved by use of top quality components throughout, and rigid inspection during production.

All standard models or modifications thereof can be furnished to meet MIL-E-18400F.

CIRCLE 106 ON READER SERVICE CARD

CIRCLE 105 ON READER SERVICE CARD
The temperature of things is so important to some people that a few degrees one way or another is a calamity: it has to be plus or minus a few tenths of a degree, or else. This group includes Deutsche beer drinkers, those who watch over crystal oscillator ovens, certain environmental test boxes, delay lines, and the Miami* tourist trade. To them, we offer a solution.

It's a Sigma Magnetic Amplifier Relay, one-half of a resistance bridge, and a built-in DC power supply—all neatly packaged and ready to go as soon as a thermistor and reference resistor are connected to complete the bridge. In operation, a temperature change unbalances the bridge, energizing the relay through the magnetic amplifier. What you do with the relay output—for corrective action or indication—is up to you. (The contacts are SPDT and available for switching 1 amp. or 5 amp. loads.)

The reason you supply the thermistor is that you know how much mounting space there is, what temperature range has to be monitored, and how much power the thermistor can safely dissipate. The woods are full of thermistor suppliers and the “Series 8000 Thermistor Temperature Control” Bulletin contains a useful guide to thermistor selection.

Compared to other ways you could detect and do something useful with changes as small as 0.1°C, this device is guaranteed free of locking contacts, delicate mechanisms and other life-shortening elements. It also provides resettable control, as well as accurate “remote” control even when fairly long leads from the thermistor are used.

Since this temperature control is about 83% magnetic amplifier, this seems like a good place to give a plug to Sigma Magnetic Amplifier devices in general. We can sell you regular and souped-up 60 cycle models, and have in development a 400 cycle type in a hermetically sealed case. All are rugged, microwatt-sensitive switches particularly useful as current, voltage or resistance comparators for monitoring or controlling light intensity, radiation level, pressure, vacuum, line voltage, etc. Bulletins on any of these are available on request.

*In South Braintree, the temperature today is 270°K.

do you know what's expected from semi-conductor materials?

There were more than a dozen articles on semi-conductor materials in electronics in recent months. Each was specially edited to give you all key facts, ideas or trends—and there's more coming! Accurate electronics' reporting tells you what's happening now, what's expected in materials and components. Don't miss dozens of articles on basic subjects edited to keep you informed, help make your research, development, sales and marketing plans pay off. It pays to subscribe to electronics (or renew). Fill in box on Reader Service Card now. Postage free.

FIND WHAT YOU NEED IN electronics
HAZELTINE RESEARCH CORP., a subsidiary of Hazeltine Corp., has opened a new research and development center in Plainview, N.Y.

Three major departments have been formed at the Plainview laboratory. The Systems Research group is concentrating on advanced radar systems, military communications and space guidance systems. The Industrial department is working on electronic applications to photographic processes and other fields. The Apparatus and Circuit Research department is devoting its efforts to semiconductor applications, electroluminescence and microminiaturization.

Jennings B. Dow, president of Hazeltine Research Corp., is coordinating activities of the three groups. He is a director of the Electronic Industries Association, and during World War II was chief of the Electronics division of the U.S. Navy's Bureau of Ships.

R. K. Hellmann is technical director and vice president of Hazeltine Research Corp. Frederick R. Lack is a consultant to the Plainview laboratory and a director of HRC.

Establishment of the Plainview laboratory was planned to strengthen Hazeltine's position in the military and civilian electronics fields, says Dow.

Hazeltine was founded in 1924 to develop the radio inventions of Prof. Alan Hazeltine of Stevens Institute of Technology. He is currently a consultant to Hazeltine Research Corp.

GI Semiconductor Expands Staff

As part of an expansion and reorganization of General Instrument Corporation's Semiconductor Division, a series of promotions and engineering staff additions have been announced by Maurice Friedman, vice president and general manager of the division. They include:

Eric J. W. Evans, named chief germanium diode process engineer. He served as a supervisory semiconductor engineer with Edison Electric Co., in England, and CBS-Electronics in the U.S.

E. Thomas Middleswarth, chief glass technologist. He joined GI in 1960, and was formerly a glass specialist with CBS-Hytron Corp., Pittsburgh Plate Glass Co. and Corning Glass.

Ralph H. Garten, appointed senior industrial engineer. He previously was mechanical design and production supervisor with Clevite Transistor Products Co.

Lawrence P. Goetz, named senior process engineer. With GI since 1953, he formerly was production engineer with P. R. Mallory Co.

Kurt J. Sonneborn, appointed senior process engineer. A chemist by profession, he is experienced in silicon and germanium device development.

Morgan Heads Up New Company

Henry Morgan was recently elected president and general manager of Electronic Controls Inc., Stamford, Conn., a recently formed company engaged in design, manufacture and marketing of automation equipment and control systems for military and industrial applications.

The newly elected president served in management capacities for eight years with Burdy Corp. of Norwalk, and five years at Gorn Electric Co. of Stamford.

GE Announces Realignment

The General Electric Co. recently announced an organizational realignment in its electronic and defense businesses.

The company's Electronic, Atomic and Defense Systems group has been renamed the Electronic and Flight Systems Group. The
A COMPLETE LINE OF MICRO-MINIATURE RELAYS "OFF-THE-SHELF"

COMPETITIVELY PRICED

Available in prototype or production quantities from your nearby sales agency. Will fill most of your applications saving you time and money.

SERIES KXI MICRO-MINIATURE

(.40 Max. x .875 x .40 Max.)

Equipped with standard DPDT 2 amp contacts rated to carry any load from dry circuit to full rating. Features at 1" grid spaced header. Nominal operating power—250 milliwatts.

New torsional rotation balanced armature offers 200,000 cycle vibration and 500 shock immunity. Proven reliability under all environmental conditions.

Quantitative Measurements Using Sweep Frequency Techniques

Model 900A—THE MOST VERSATILE SWEEP GENERATOR $1,260.00
CENTER FREQUENCY—VHF 0.5 to 400 MC
UHF 275 to 1000 MCS—SWEEP WIDTH—up to 400 MCS—FLATNESS—±0.5 db over widest sweep

Model 707—ULTRA FLAT SWEEP GENERATOR $795.00
Featuring ±5/100 db flatness—Plug-in osc. heads*; variable sweep rates from 1/min. to 60/sec.; all electronic sweep fundamental frequencies; sweep width min. of 1% to 120% of C.F.
*Heads available within the spectrum 2 to 265 MCS

Models 601/602—PORTABLE GENERAL PURPOSE $295.00
COVERAGE—Model 601—12 to 220 MCS. Model 602—4 to 112 MCS—FLATNESS — ±0.5 db OUTPUT—up to 2.5 V RMS
WIDTH—1% to 120% of C.F.

Model FD-30 $250.00
High speed DPDT co-axial switch permitting oscilloscope measurements without calibration—all measurements referenced continuously against standard attenuators.

Model AV-50 Variable Precision Attenuator $150.00
Long life rotary switches; dual wiping silver contacts on "Kel-F" dielectric, 0-62.5 db in 1/2 db steps; DC to 500 MCS.

Suomala Joins Gabriel as V-P

APPOINTMENT of John B. Suomala as vice president of engineering of the Gabriel Electronics Division of The Gabriel Co., Millis, Mass., has been announced. Formerly with the Instrumentation Laboratory at MIT, he has had over 15 years engineering and managerial experience in his field.

At MIT for five years, Suomala had staff and line responsibilities for many projects including: inertial guidance systems in connection with ICBM programs; automatic ground environment systems; and...
Types 6AR and 6DR incorporate plug-in lamp

ELDEMA SWITCHLITES

Designed and built to meet or exceed all applicable military specifications, ELDEMA's versatile family of miniaturized push-to-test SWITCHLITES are furnished with either SPST or DPDT switch configurations . . . and incorporate a wide variety of permanent or replaceable lamps. Neon or incandescent lamps, with optional voltage ratings, can be supplied. These four ELDEMA Switchlites complement one another for applications in data processing circuits, control systems, test equipment, computers . . . and in circuitry involving unique and specialized switch/light parameters.

ELDEMA CORPORATION 1805 Belcroft Ave. El Monte, Calif.

1ERX-DLA-T transistorized Switchlite

Incorporating a transistorized neon driver and switchmade at a plug-in assembly, the 1ERX-DLA-T satisfies the need for low-voltage circuit triggering of neon indicators.

Ideal for fail-safe applications, the 6AR enables two separate circuits to be monitored without a common connection. Lamp and switch terminals of the 6DR are brought out separately in a 4-pin socket.

Type 6B

The miniaturized 6B is designed so the lamp and switch can be used separately or in combination with one another.

furnished with replaceable lamp and large plastic lens

Appoint Dole
R&D Director

ACE ELECTRONICS ASSOCIATES, INC., Somerville, Mass., manufacturer of precision potentiometers, has appointed Fred E. Dole director of research and development of the corporation and its affiliates. His responsibilities include supervision of all matters of design, prototyping and production.

Dole has been a consultant to the electronic industry in the fields of precious metals, contacts, switches and other electromechanical component areas. For the past twelve years, he has acted as director of the Industrial Division of the J. M. Ney Co., Hartford, Conn. He served also as consultant for customer engineering for the Ney firm on a national basis, prior to establishing his own consulting firm.

Du Pont technical know-how, backed by years of research and experience, can help you find the right answer to your specific coating problems. Du Pont conductive coatings...of silver, gold, platinum, palladium...are available to you for use on almost every type of electronic circuit and component:

- Electrodes for barium titanate ceramic capacitors.
- Electrodes for mica capacitors.
- Electrodes for thermistor and piezoelectric bodies.
- Air dry static shields and conductive coatings.
- Thermosetting conductive cements for metals, phenolics, epoxies and other bases.
- Fired coatings on ceramic and glass (e.g., when copper-plated and tinned for hermetic sealing).

Write for bulletin on high-quality Du Pont Conductive Coatings of Silver, Gold, Platinum and Palladium. Mention application you have in mind. Du Pont has a formulation to fit your application, process or product features. Write: Du Pont, Electrochemicals Department, Ceramic Products Division, Wilmington 98, Delaware.

INERTIAL SYSTEMS DEVELOPMENT

...there are opportunities at Honeywell for the engineer or scientist who is interested in participating in this growing field of technology. While specific inertial systems experience is desirable, you may also be qualified by your background and/or related experience for activities in the inertial systems development at this time. Specific openings include:

SYSTEMS ANALYST

Mathematician or engineer with strong background in vector analysis, operational calculus, matrix algebra and related techniques. To carry out analysis of inertial systems configurations including error evaluation.

DIGITAL SYSTEMS AND LOGIC DESIGNER

Familiar with digital logic techniques at current state of the art; capable of organizing computing systems to perform various tasks including logical design and critical parameter specification.

ELECTRONIC ENGINEER

Electrical engineering degree plus experience in miniaturized semiconductor electronics development. To design servo, pickoff, and other electronics for use with gyro and accelerometers.

ENGINEERING PHYSICIST

Physicist with practical and theoretical understanding of mechanics, magnetism and electricity to analyze and develop inertial sensors of novel and original design.

To discuss these or other openings, write Mr. R. O. Maze, Chief Engineer, Marine Systems Group, Dept. 214-A, Aeronautical Division, 1433 Stinson Blvd., Minneapolis 13, Minn.

Honeywell

To explore professional opportunities in other Honeywell operations coast to coast, send your application in confidence to R. K. Eckstrom, Honeywell, Minneapolis 8, Minnesota.

RAYSHEON

Excellence in Electronics

COMMERCIAL

APPARATUS & SYSTEMS

Senior Microwave Engineer

You will be given system responsibility for the development of new concepts in the generation, propagation and absorption of microwave power for heating, cooking and curing purposes, in numerous commercial and industrial applications. (Raytheon is one of the few electronics companies whose staff includes systems, advanced development, and design engineers in these fields.)

You must have a BSEE or equivalent and should have 8 years of broad design or advanced development experience in the microwave field in order to handle the planned assignments. (Experience in radar development, for instance, or DC power generators or magnetrons.) Since we're looking for an exceptional individual—who will be rewarded accordingly—the deciding factor will probably be your creativeness and ingenuity, as evidenced by: patent disclosures; significant publications; or descriptions of accomplishments not formalized by patents or publications.

Microwave Licensee Engineer

You will serve as liaison between Raytheon and licensees, assisting in the design of microwave cooking units for these licensees' commercial ovens. This will involve working with the licensees' design engineers to solve such problems as heat, sanitary considerations, microwave distribution, wave modulation, insulation and cost reduction. You will also help translate licensees' suggestions into product improvements.

You should be a senior-level electronics engineer with a BSEE or equivalent and should have 5 years' applicable experience. Background in design of test equipment, high-power modulators, or commercial microwave equipment is especially useful, as is knowledge of magnetrons, underwriters' requirements and FCC regulations. Basically, we're looking for a top design and sales engineer (travel will be limited, however) so salary is commensurate—that is, excellent.

Both positions are in the suburban Boston area and offer attractive cultural, educational and recreational opportunities. Relocation assistance is available. Please phone collect (Bigelow 4-7500) or forward your detailed resume to Mr. Paul R. Alexander, Manager of Professional Personnel, Commercial Apparatus & Systems Division, Raytheon Company, Watertown, Massachusetts.

EMPLOYMENT OPPORTUNITIES

COMMERCIAL EXPANSION AT NATIONAL CREATES

IMPORTANT DIGITAL COMPUTER R&D POSITIONS IN LOS ANGELES

TRANSISTOR CIRCUITS ENGINEERS —
Senior and Intermediate
Highly creative positions are available in circuit analysis and design. Duties include advanced mathematical studies in transistor circuitry, evaluation of transistor circuitry, component studies and keeping abreast of computer circuit advances. Circuit analysis ability and solid understanding of transistor theory essential. E.E. degree required.

ELECTRONIC DESIGN ENGINEERS —
Senior and Intermediate
To form new group in design of general-purpose digital buffers. Three to five years' logical and transistorized circuit design of digital equipment preferred, with additional background in ferrite magnetic core memories.

ELECTRONIC PRODUCT DESIGN ENGINEERS
To form nucleus of a new product engineering and manufacturing liaison group. Positions require 2-3 years of electronic design experience, preferably in digital computing equipment or transistor circuits.

SENIOR PROGRAMMERS
For development of advanced automatic programming techniques for a general-purpose data processor, acceptance testing, etc. Experience should include construction of auto codes, service-type routines, simulators or diagnostic routines.

TEST EQUIPMENT ENGINEERS —
Senior and Intermediate
To form nucleus of new electronic digital test equipment design-development group. Applicants must have at least 3 years' pertinent experience and some familiarity with digital applications of transistors and/or magnetic cores.

RECENT GRADUATES
Excellent opportunities for recent graduate engineers with 6-18 months' experience. Positions are in the areas of transistor circuit and magnetic circuit techniques, logical design.

Please send resume to N. E. Powell, Personnel Manager

The National Cash Register Company
ELECTRONICS DIVISION
1401 E. El Segundo Blvd., Hawthorne, Calif.

EMPLOYMENT OPPORTUNITIES

not just another pebble...

at magnavox there's no getting lost in the crowd.

As an engineer in our government and industrial divisions, you stand out as an individual with ideas. Ideas that we listen to. Ideas that are put into motion. Ideas that step you ahead... fast.

But while we gladly admit to NOT being a giant, neither do we take a back seat to anyone in the kind of creative climate we offer engineers. We are, in fact, currently engaged in a vast number of highly specialized areas of electronic activity and our customers rank among the principal names in business and government both here and abroad.

At present, we need engineers to carry on expanding programs in communications, airborne radar, missiles, anti-submarine warfare systems and data processing equipment. The projects we have on tap are broad and challenging. The men we offer as your associates are high caliber creative scientists like yourself. And the technical facilities we provide are the finest, most complete anywhere.

If you're a man who likes to accept challenge—and wants to be recognized for it—we'd be glad to hear from you. Phone Dick Eary (collect, of course) at Eastbrook 9721 in Fort Wayne or write him today for complete information.

Opportunities in Development

New developments in Esaki Diode technology at IBM

The Esaki Diode at left was made experimentally.

Soon after the original discovery of the Esaki Diode, IBM engineers and scientists began a thorough investigation of its properties. As a result of this investigation, IBM has evolved new techniques to improve some of its most important characteristics. A stage of development has been reached where germanium Esaki Diodes can be made with peak-to-valley ratios averaging between 14 and 15 to 1, and with peak currents that can be controlled within 1%.

Looking at All Aspects
At IBM, the Esaki Diode is being examined from many viewpoints. Physicists and mathematicians are studying the theoretical foundations of its behavior. Other scientists and engineers are probing its electrical characteristics. Still others are refining techniques for its construction.

It takes the varied skills of many engineers and scientists to advance the state of new and complex technology. It also takes the inherent progressive spirit of an organization interested in making these advances.

Careers in Frontier Fields
Solid state studies may not be your primary interest. You may have specialized in other areas of engineering, or in one of the sciences. But whatever your goals or your background, you'll find opportunity for fascinating work in frontier fields at IBM's expanding research and development laboratories.

If you have a degree in engineering, mathematics, or one of the sciences—plus experience in your field—write, briefly outlining your qualifications, to:
Manager of Technical Employment
IBM Corporation, Dept. 554Q1
590 Madison Avenue, New York 22, N. Y.
EMPLOYMENT OPPORTUNITIES

A Major New Power In Electronics Is Born

The recent formation of LOCKHEED ELECTRONICS COMPANY marks the beginning of new expansion—entry into new markets and new activities in both military and non-military fields.

On the East Coast, Lockheed Electronics Company has organized 3 operating divisions. Immediate positions are available for experienced engineers and scientists who possess proficient experience in the following activities and who desire unlimited professional growth with a dynamic, new and expanding organization.

Military Systems-Stavid Division
STAVID will continue to expand its present capabilities in military electronics, and will place special emphasis on: Airborne ASW research and development; Sonar; Sonobuoy systems; unique underwater detection devices; advanced radar systems; operations research—systems analysis; ECM and digital computer design.

Information Technology Division
This new division is engaged in the development and marketing of data systems and sub-systems including: data processing, storage and display systems; telemetry; special purpose computers; systems analysis; communications and navigation systems. Special demand for solid-state circuit design engineers with particular emphasis on DC amplifier and low level, low noise amplifier design; VCO and FM discriminator design experience.

Engineering Services Division
(FIELD OPERATIONS) will continue to expand and diversify in the areas of product service, test, evaluation, range instrumentation and operation, high quality engineering and consulting services. Current professional opportunities immediately available on programs involving: experimental data processing equipment; simulators and trainers; radar and navigation systems; missile guidance and associated general support equipment.

If you would like to investigate present and future opportunities in this growing company, you are invited to submit your professional resume in confidence to:

FUTURISM in contemporary R&D

Radical departures from traditional forms of scientific investigation are the keynote of Republic Aviation's forward-looking programs in space exploration and upper atmosphere flight. In an environment that regards with skepticism the seeming validity of conventional conclusions, engineers and scientists seek below-the-surface solutions of problems...bypassing the superficial.

Expanding the scope and depth of present programs is Republic's recently completed $14 million Research and Development Center. Extensive facilities here are an invitation to professional men to realize the future by solving today's most perplexing problems.

SENIOR LEVEL OPENINGS EXIST IN THESE IMPORTANT AREAS:

- Solid State & Thermionic Devices / Microwave Circuitry & Components / Countermeasures
- Digital Computer Development / Radome & Antenna Design / Receiver & Transmitter Design / Miniaturization / Transistorization
- Microwave Circuitry & Components / Digital Computer Development
- Analog Design Systems Engineering Digital Design
- Project Management Systems Engineering
- project Engineering System Evaluation and Modernization
- Field Engineering

If you'd like to receive more information about us, we suggest you write to our Mr. J. W. Carlton enclosing a brief description of your background.

  ELECTRONICS BUYERS GUIDE for complete line
  of products or services.

HUGHES in FULLERTON has immedi-
ate Research & Development open-
ings for circuit designers, logical
 designers, programmers and analysts
for the development of large scale
information processing systems, in-
cluding new general purpose and
special purpose computers. Assign-
ments exist in the following areas of
specialization:

GENERAL PURPOSE COMPUTER SYSTEMS
• Microwave Carrier Logic
• Millimicrosecond Base-Band Logic
• Tunnel Diodes
• Evaporated Magnetic Components
• Micro-Electronic Techniques
• Transistor High-Speed Gating
• Techniques
• Solid State Circuits
• Core Memory and Buffers

ARMY/NAVY COMPUTER SYSTEMS
• Systems Analysis and Evaluation
• Operations Research
• Self-Test and Maintenance
• Engineering
• Logical Design
• Transistorized Digital Circuits
• Digital Memory Devices
• Advanced Displays
• Servomechanisms and Feedback
  Amplifier Design
• Digital Data Organization and
  Transmission
• Voice Communication and
  Modulation Techniques

MORE RELIABILITY and
BETTER PERFORMANCE with
FREED QUALITY
IN STOCK FOR IMMEDIATE DELIVERY

CONSTANT VOLTAGE TRANSFORMERS.

Meets Military Accurate Regulations No Tubes No Moving Parts
Specifications Fast Response Fully Automatic
MIL Type Commercial Type

Here at last is a hermetically sealed magnetic voltage regulator that will provide constant output voltage regardless of line and/or load change.

SUPPLIED EITHER MIL OR COMMERCIAL

MAGNETIC AMPLIFIERS

- Hermetically Sealed To MIL Specifications
- No Tubes
- Direct Operation from Line Voltage Fast Response
- Long Life Trouble Free Operation
- Phase Reversible Output:
  - Power Gain 2 x 10^4

MAT-1 Wt. 10 oz.

Precision Film advantages offered economically by IRC Stabaloy* Resistors with TC not exceeding 150 ppm

IRC Stabaloy resistors feature an element produced by an exclusive IRC process. It is free from the inherent problems associated with wire wound precision resistors, and provides a saving of over 50% in size and weight. Capacitance and inductance are inherently low so that Stabaloy resistors are ideal for high frequency applications. Voltage coefficient is negligible.

IRC Stabaloy resistors have a maximum temperature coefficient of ±150 ppm, and they provide the operating characteristics of precision resistors costing much more. IRC Stabaloy resistors are available in 3 standard sizes—1/8 watt, 1/4 watt and 1/2 watt. The illustrations above are actual size. Standard tolerance is ±1.0%. Tolerance of ±0.5% is available. For most of the advantages of precision film resistors at an economical price, examine carefully the characteristics of IRC Stabaloy resistors. Write for Bulletin AE-10. International Resistance Co., Dept. 375, 401 N. Broad St., Philadelphia 8, Pa.

The Famous RCA Tube Handbook HB-3...bible
of the electronics industry...marks its Silver Anniversary Year in 1960

For a quarter-century the famous RCA HB-3 Tube Handbook has played a key role in the amazing growth of electronics. Starting in 1935 as a single binder of some 200 pages, it has grown to a five-binder set containing over 4,200 pages of indispensable electron tube data—the most authoritative, respected reference of its kind. Its young companion volume, the HB-10, gives similar data on semiconductor devices.

To help put the world of electronics at your fingertips, consult these handbooks for vital data on RCA electron tubes and semiconductor devices. Subscription information is available from your Authorized RCA Electron Tube and Semiconductor Products Distributor, your RCA Field Representative, or RCA Commercial Engineering, Section E-19-DE, Harrison, N. J.
