SEMI-AUTOMATIC BRIDGES for PRODUCTION TESTING

* Fast . . . Self Balancing . . . Measurements are made as rapidly as components can be connected.
* Rugged mechanically and electrically for continuous production-line use . . . Built to laboratory-equipment standards.
* Easy to operate . . . Once set up, no further adjustments are necessary; measuring procedure reduces to simply connecting unknown to Bridge and reading meters.
* Widely used as basic measuring elements in automatic sorting equipment.

For D-C Resistance Measurements

Type 1652-A Resistance Limit Bridge . . . $520

Large, easily-read meter indicates directly component resistance as a percentage of value of internal standards. No computations, minimum possibility of mistake, saves valuable testing time.

Range: 1 to 1,111,111 ohms with internal resistance standard. 1 ohm to 2 megohms using external standards.

Meter Range: Meter reads from −20% to +20%.

Accuracy: As a limit bridge, 0.5% or better. For matching resistances, = 0.2%.

Three High-Sensitivity Models providing full-scale ranges of ±2%, ±5%, and ±10% can be supplied on special order.

Write For Complete Information

GENERAL RADIO COMPANY
WEST CONCORD, MASSACHUSETTS

For R, L, C, and Impedance Measurements

Type 1605-A Impedance Comparator . . . $800

Indicates directly on two panel meters the differences in magnitude and phase angle between an unknown and an external standard. Measures impedance differences as small as 0.01% and phase angle differences of ±0.0001 radian.

Ranges: Impedance and resistance, 2 to 20 MΩ. Capacitance, 40 μF to 800 μF. Inductance, 20 μH to 10,000H.

Meter Ranges: Impedance Magnitude Difference: ±0.3 %, ±1%, ±3%, ±10% full scale. Phase-Angle Difference (in radians): ±0.003, ±0.01, ±0.03, ±0.1 full scale.

Accuracy: 3% of full scale; i.e., for the ±0.3% range, accuracy is ±0.009% of the impedance magnitude being measured.

Internal Oscillator Frequencies: 100c, 1 kc, 10 kc, 100 kc.
THE COVER SHOWS a typical computer circuit and its realization as a microminiature package of semiconductor networks. Different circuits have been fabricated from blocks of semiconductor material by various combinations of oxide masking, diffusion, alloying, metal deposition and surface shaping techniques. The selected example includes flip-flops, pulse inverters and diode gates. When these units are interconnected as shown in the fold-out, the resultant subassembly occupies 0.013 cu in. and weighs 1.3 gm. The concept of a semiconductor network involves the relation of conductance paths in a semiconductor to classical circuit elements. This enables an orderly design approach that starts with the existing knowledge of circuit theory. Semiconductor networks are a major departure from conventional components because active and passive circuit elements are integrated into single-crystal semiconductor wafers. Protection and packaging of individual elements are eliminated. Lead wires and interconnections are reduced by as much as 80 percent. Fabrication steps have been reduced to one-tenth of those required for the same circuit function using miniature components. The result is a realistic solution to the reliability, space, weight and cost problems in microelectronic systems. Turn to page 69 for additional information on semiconductor networks.
Semiconductors and Solid State

SEMICONDUCTORS, the curiosities of 1950, are shelf products today. And combinations and configurations of semiconductors are being combined in solid state devices and packages so small that magnifying glasses are becoming necessary equipment in our editorial department as well as in many laboratories.

Our art director had some miniaturized headaches preparing the photographs and drawings which accompany the article beginning on page 69 of this issue. This article is another in a long line of ELECTRONICS firsts, being an exposition on solid state circuits revealing theory, design and fabrication in detail. There will be others in the months ahead. Also, in the months ahead, semiconductor shelf items will adjust downward from present prices as volume, improved technology and the forces of competition exert their influences.

Among subscribers to ELECTRONICS, the next-best-read business magazine is the McGraw-Hill publication Business Week. An outstanding report on semiconductors appeared in the March 26th issue of that publication. If you are one of our subscribers who also reads BW, you have seen it. If you haven’t, a reprint may be obtained for 50¢ by writing to Reprint Dept., Business Week, 330 West 42nd Street, New York 36, N. Y.

EMPIRE
COAXIAL ATTENUATORS

Rated up to 4 Watts

Empire attenuators have been designed and constructed for the reliable performance so essential to modern, complex systems. Their rugged construction . . . conservative power ratings for CW and pulse operation . . . and exclusive deposited carbon precision resistors . . . enable them to satisfy your microwave attenuation requirements.

Resistive coaxial networks shown here are intended for operation up to 4000 MC, a complete line of coaxial attenuators to 10,000 MC also available, and is described in our Catalog No. 604. Low VSWR and high accuracy are inherent features. Attenuation values up to 60 DB are obtained in individual pads, rated up to 4 watts continuous and 2 KW peak (AT-75) or as six and twelve position step attenuators (AT-108, AT-109). With two or three attenuators connected in series, values up to 120 DB can be obtained.

In many cases our engineering files contain a ready solution to your unusual coaxial attenuation problems.

For complete technical information, write for free Catalog No. 604.
C TYPE MAGNETS in a wide range of sizes to meet your design needs in

- Transverse Field Isolators
- Differential Phase Shifters
- Duplexers

Arnold C-type Alnico Magnets are available in a wide selection of gap densities ranging from 1,000 to over 7,500 gausses. There are six different basic configurations with a wide range of stock sizes in each group.

The over-all size and gap density requirements of many prototype designs can be met with stock sizes of Arnold C Magnets, or readily supplied in production quantities.

When used in transverse field isolators, Arnold C Magnets supply the magnetizing field to bias the ferrite into the region of resonance, thus preventing interaction between microwave networks and isolating the receiver from the transmitter. These magnets are also used in differential phase shifters and duplexers, and Arnold is prepared to design and supply tubular magnets to provide axial fields in circular wave guides.

A feature of all Arnold C Magnets is the excellent field uniformity along the length of the magnet. Versatility in design may be realized by using multiple lengths of the same size magnet stacked to accomplish the needs of your magnetic structure.

Let us work with you on any requirement for permanent magnets, tape cores or powder cores. For information on Arnold C Magnets, write for Bulletin PM-115. Address The Arnold Engineering Company, Marengo, Illinois.

PROJECT DEFENDER. The technical problems that must be solved to defend the U. S. against nuclear armed vehicles from outer space probably pose the greatest challenge to the electronics industry to date. How is the Advanced Research Projects Agency, which is responsible for the task, attacking the problem? What approach is ARPA taking and who is doing the work?

Associate Editor Mason talked with ARPA, Army, Navy, Air Force and industry. Associate Editor Solomon helped fit into place the pieces in our story about this gigantic and vital project. It begins on p. 36.

NEXT SEASON'S TV. Next season's television sets are being polished and groomed for showing at distributor conventions this month and next. Most manufacturers are keeping the details under Detroit-style wraps, but some clues are plainly evident: There will be more color sets introduced this year. The resulting competition is expected to reflect in the consumer's favor. In black-and-white lines, more attention will be given to custom furniture. There will be new models of portable sets, and many more of these will be equipped for remote tuning. One scrap shaping up centers around bonded vs unbounded picture tubes. Associate Editor Emma has been talking to manufacturers in five states. For the details of what he learned, turn to p. 44.

Coming In Our May 20 Issue

SPACE COMMUNICATIONS. The problem of transmitting electromagnetic energy through ionized regions is becoming increasingly important to designers of communications and guidance equipment for nuclear vehicles, hypersonic re-entry vehicles, and equipment which must operate in a nuclear or high-temperature environment. Blackout of signals from re-entry vehicles, attenuation of electromagnetic energy through rocket motor exhausts, and transmission through a nuclear fireball are all mechanisms which must be understood by engineers who must work to specific requirements. In next week's cover story, W. A. Greenhow of Chance Vought Aeronautics discusses theoretical and experimental aspects of these ionization mechanisms.

MISSILE TRACKING. When test firings are made on the Atlantic Missile Range, missiles are followed during the power flight portion of their trajectories by a combination of an optical telescope (ROTI) and an infrared rapid scan system. Description of the ROTI system was published in our Jan. 16, 1960, issue (p 47). Now, Joseph Day, Jr., of the Perkin-Elmer Corp., who has been working on a series of ROTI missile tracking systems, brings readers a description of his firm's i-r rapid scanning system which makes spectrometric studies of missile flights, and which may eventually help in identifying missiles by their plume characteristics. The rapid-scan system consists of a monochromator, a radiation detector system and readout equipment. The spectrometer employs a double-pass Littrow optical system to feed energy to a detector whose signal is then used to produce a function-of-time plot.

FILTER DESIGN. If you're an engineer who has been designing filters, you'll want to read and clip out for your file the article by Kurt Lichtenfeld of Hughes Aircraft Co., on how to simplify your Zobel filter design problems by the use of Cauer parameters. Author Lichtenfeld describes this design method for low-pass, high-pass, bandpass and band elimination filters, and provides example problems for each type.
Now you can get fast delivery from stock of popular Oak rotary switches.

Order them as completely assembled units or as subassemblies in quantities from 1 to 249. All stock switches have one fixed and one adjustable stop; grooved shafts for "break-off" to desired length; double-wiping contacts of silver-plated brass (shorting and nonshorting types). Finishes withstand the 50-hour salt spray test, enabling the switches to be used in most military as well as commercial applications.

These are the same, quality OEM switches which have formerly been available only as custom units in large production quantities. For years they have been the industry's standard in all types of electronic equipment.

Don't wait, call your Oak representative or the factory for complete details today.

COMMENT

Kudo In Advance

I was delighted to learn that you are planning to devote a major part of the May 27, 1960 issue of ELECTRONICS to a review of the technology of the electronic industries of Japan. We feel that this will be an invaluable service to members of the electronic industries of the United States.

In the Department of Commerce, we feel that developments in electronics in Japan are so important that I am spending several weeks here meeting with Japanese industrialists discussing these matters—just as I have done previously in the centers of electronics activities in Europe. By the way, officials of the Japanese Government (both in Washington and Tokyo) have been most cooperative in connection with my visit.

I should like to offer my commendation for your undertaking to publish this special issue of ELECTRONICS.

DONALD S. PARRIS
Director
ELECTRONICS Div., BDSD
U. S. DEPT. OF COMMERCE

Reader Parris, also well out in front, wrote to us on stationery of The Foreign Service of the United States of America, from Tokyo. Below (also from Japan) see photo of Associate Editor Frank Leary, whose report, "Electronics in Japan," appears May 27.

Monopulse Radar

A number slipped in the radar designation in the caption in "Precision Tracking With Monopulse Radar," p 51, Apr. 15. The correct designation for the radar is AN/FPS-16, not AN/FPS-6.

JOHN F. DUNN
DEAN D. HOWARD
WASHINGTON, D. C.

New Format

Plaudits on your new format. I have been a reader of ELECTRONICS for more years than I care to admit, and think your latest issue represents the biggest step forward in terms of layout that I have yet seen in the magazine.

I'm glad to see color on the cover and hope that it will be a regular item in following issues. It gives your magazine the appearance of high quality that the inside material rarely fails to back up. Fine work!

R. E. COLWELL
OLD TAPPAN, N. Y.

... We received a copy of your special issue on vacuum tubes today (Apr. 29), and from a layout point of view it's one of the best-looking business papers we've ever seen. And the editorial material is excellent. . . .

C. M. Clough
TEXAS INSTRUMENTS
DALLAS

Japan's Telephone System

In "Japan Develops New Computer Logic" (p 36, Apr. 15) you describe Nippon Tel & Tel as a government communications utility. I though IT&T ran the phone service in Japan.

H. N. STOVER
HADDONFIELD, N. J.

Confusion naturally arises because IT&T has an affiliate in Japan, and because the overseas phone and cable service is handled by Kokusai Denshin Denwa, which means International Telephone & Telegraph but which is another government communications utility.
1200°—Yet No Catastrophic Failure With New Electra Precision Carbon Film Resistor

Check at right the histograms showing test results on the new Electra Precision Carbon Film Resistor. See for yourself the remarkable ability of this resistor to withstand extreme conditions of heat and humidity, also its exceptional load life. Primary credit for these outstanding characteristics goes to Electra's exclusive new Type R-5 coating, developed in our laboratory after a long period of scientific study and experimentation. But performance alone is not the whole story. Check, too, the sizes; truly, this resistor opens up a whole host of new possibilities in your design and engineering work.

measure and supply DC voltages to 0.02%

with the new KIN TEL DC voltage standard and null voltmeter

LABORATORY ACCURACY. The Model 301 is an extremely compact and accurate variable DC power supply and calibrated null voltmeter. It employs KIN TEL's proved chopper circuit to constantly compare the output voltage against an internal standard cell. As a DC voltage standard, it combines the stability and accuracy of the standard cell with the current capabilities and excellent dynamic characteristics of the finest electronically regulated power supplies. The self-contained null voltmeter indicates the voltage difference between the supply in the 301 and the DC source being measured, affording simple and rapid measurement of DC voltages to an accuracy of 0.02%.

PRODUCTION LINE SPEED. DC voltage measurements can be made as fast as changing ranges on a VTVM. Merely set the direct reading calibrated dials on the 301 to exactly null out the unknown DC input voltage. The reading on the dials then indicates the value of the unknown input voltage to within 0.02%. As a variable DC standard or power supply, the calibrated dials provide instant voltage selection to an accuracy normally attained only with standard cells.

VERSATILITY. The KIN TEL Model 301 is ideal for rapid and accurate production calibration of precision measuring instruments and DC power supplies... design of DC amplifiers and complex electronic circuitry... computer reference... versatile precision reference for calibration and measurement laboratories.

IMPORTANT SPECIFICATIONS

Output Voltage & Current 1 to 501 volts at up to 20 ma
Full Scale Meter Ranges (Zero Center)
DC Output Range ............ ±500, 50 volts
DC Input Range ............ ±500, 50 volts
DC Null Meter Range ........ ±50, 5, 0.5, 0.05 volts
Long Time Stability ........ ±100 parts per million
Output Voltage Calibration .... ±0.02% or 2 mv
Output Hum and Noise ...... Less than 100 µV RMS
Line and Load Regulation ....... ±0.002%
DC Output Impedance ...... Less than 0.01 ohm
Response Time .................. 0.2 millisecond
Model 301 or Model 301R (Rack Mount) Price $795.

0.01% stability
0.02% accuracy
1 to 501 volts at 20 ma
4 accurate null ranges
0.002% regulation
Less than 100 µV ripple

KIN TEL manufactures electronic instruments for measurement and control, and closed circuit TV. Representatives in all major cities. Write for detailed literature or demonstration.

ELECTRONICS NEWSLETTER

Navy Survey Predicts
Sales Up $1.3 Billion in 1960

A Navy survey of 585 electronics companies engaged in end equipment production indicates that the 1960 projected sales output will be about $10.9-billion. This would continue the trend of rising output each year.

Sales were up in 1959 to $9.6-billion as compared with $8.3-billion in 1958. The 1959 figure was within 21 percent of the sales predicted by industry a year ago. The figures were revealed in a report prepared by the electronics section of the Office of Naval Material.

Production for the military in 1960 is expected to be $5.9-billion as compared with $5.1-billion last year. Total military backlog as of Jan. 1 was $5.7-billion of which approximately $4.4-billion was in prime contracts and $1.3-billion in subcontracts. The backlog figures were approximately the same as a year ago.

Total number of employees climbed up to 578,000 from 514,000 a year earlier. Average sales per employee increased from $16,000 to $16,600.

The industry could produce with its present facilities (building space, machinery, etc.) $14.1-billion in one shift by merely adding people as compared to $12.6-billion a year ago, ONM estimates.

New Business Data Processor Reads Standard Terminology

Keen interest in its newly developed NCR-390 system is reported this week by National Cash Register, an active entrant in the small computer derby.

The system reads records prepared in standard business terminology from four magnetic strips imprinted on the back of a ledger sheet, invoice or other commercial document. Information on the strips duplicates data on the front of the sheet. As paperwork is processed through a reader-imprinter, a paper tape is punched to serve as a permanent storage.

NCR president S. C. Allyn believes the NCR-390 will enhance his company's position in the office equipment market. So far, ELECTRONICS learns, 50 of the new machines have been sold to buyers in 20 different kinds of business operations.

Scientists Grow Transparent Crystals of Gallium Phosphide

Transparent gallium phosphide single crystals have been grown experimentally at Bell Telephone Laboratories, it was reported last week. Scientists say the structure produced will help in the basic understanding of high-energy gap semiconductors. Since the material is transparent, the differences that take place under varying conditions of doping and electron density may be observed visually.

Major problem with gallium phosphide, says BTL, is that it decomposes at temperatures near its melting point unless it is held under high pressures of gaseous phosphorus. C. J. Froesch and M. Gershenzon reported that their work has aimed at producing single crystals of the material by the floating zone melting technique. They built special equipment to withstand the high pressure phosphorous atmosphere. Single crystals about 1-in. long by 1-in. sq were obtained at temperatures of 2,640 to 2,730 F. and pressures of 10 to 50 atmospheres (overcome partly by heating the walls of the apparatus).

Small single crystals have also been grown by vapor reaction methods by Gershenzon and R. M. Millyak of BTL, who described a reaction of gallium suboxide and phosphorus in the vapor phase. The crystals—usually n-type— although they can be doped p-type—show a whisker form and exhibit free carrier concentrations of 109 to 1010 per cc, as calculated from resistivity measurements. The Bell scientists produced diffused and alloyed diodes which showed breakdown voltages as high as 35 volts, rectification ratios up to $3 \times 10^4$ and reportedly performed well up to 500 C.

NEWS BRIEFS . . .

An international subsidiary has been formed by General Telephone & Electronics. The new group will integrate all of GT&E's international manufacturing, marketing and engineering operations. President of GT&E International is Gene K. Beare. He will also have responsibility for the operations of Automatic Electric International, Inc., and its international subsidiaries. Area headquarters will be located in Geneva, Switzerland, covering Europe and the Middle East, and in Mexico City, covering Mexico and Central America.

French President Charles DeGaulle last month visited the new Hewlett-Packard plant in the Stanford Industrial Park, Palo Alto, Calif., his only visit to an industrial facility during his U. S. tour. Exec. v-p William R. Hewlett escorted DeGaulle on the 40-minute tour, reported later that the President was impressed with the range of 400 test instruments and devices made by the company, and with the complexity of component assembly. He shook hands with many employees and asked about their hours, pay and working conditions. (Photo on p 37.)

Defense Dept. is considering establishment of an information center on ceramic materials, says John R. Townsend, special assistant to the director of Defense Research and Engineering. He told the American Ceramic Society that the government was intensifying ceramic materials research, urged industry to do the same.

Low-priced tape-controlled electronic positioning system with nominal electrical accuracy of one part in 400,000 will be shown by EMI Electronics June 28 at the Machine Tool Exhibition, Olympia, London.

RELIABILITY BASED ON TWO YEARS OF MANUFACTURE

Based on the meltback technology from which have come a number of very reliable transistors, the new 2N1289 is believed to be the first germanium NPN transistor to meet the needs of high-speed computers. Thorough characterization provides all the necessary data for “worst case” designs.

The 2N1289 features a typical alpha cutoff frequency of 60 mc, and a 10 ma beta of 150. Voltage ratings are high. Emitter cutoff current and collector cutoff current are measured at 5 and 15 volts, respectively. Also, the transistor provides a high-gain bandwidth product which is virtually independent of operating point.

High voltages, together with a constant-gain bandwidth product, allow the 2N1289 to be used in a wide variety of complementary switching circuits with just about any PNP high-speed transistor. This device performs best out of saturation.

Backing up the 2N1289 is more than two years of manufacturing experience with meltback transistors. Over 100,000 of these transistors have been tested to severe mechanical and electrical standards. The survival rate has averaged greater than 99 percent.

Your G-E Semiconductor Sales Representative has complete details on the 2N1289. Call him to get all the facts on performance characteristics that make this device perform capably and reliably in high-speed computer circuits. Semiconductor Products Dept., Electronics Park, Syracuse, N. Y. In Canada: Canadian General Electric Company, 189 Dufferin St., Toronto, Ont. Export: International General Electric Co., 150 E. 42 St., New York 17, N. Y.

GENERAL ELECTRIC
WASHINGTON OUTLOOK

THE NEW DEFENSE BUDGET came through the first wringer—the House Appropriations Committee—with $122 million extra tacked on. As was the case last year, the lawmakers severely juggled individual procurement and R&D projects in which electronics contractors are important suppliers.

On the plus side, the committee boosted funds for Army modernization, transport aircraft, fighter planes, the Polaris program, and antiship submarine operations well over the Administration's budget request.

On the other side of the ledger, funds for Navy's $293-million aircraft carrier were knocked out and the Air Force's Bomarc-B project was trimmed even more than the Administration recently proposed.

Of major interest to the electronics industry was the addition of $215 million for procurement of 30 to 50 Convair F-106 all-weather fighter-interceptor planes. The Pentagon's original shopping list for next year omits new orders for this aircraft. The committee called for these electronics-laden aircraft to provide air defense for the near future "in lieu" of the gutted Bomarc program.

Another key electronic provision is the addition of $321 million for antiship submarine forces. Almost one-third of this sum is earmarked for research and development.

The committee rapped the Navy for failure to provide "dramatic or dynamic leadership" to run the antiship warfare show. The lawmakers want a "single manager" to take charge. In effect, this would be similar to the way the Polaris development program has been run—with a special project office headed by a naval "czar" autonomous of the traditional bureau organization.

The committee also took a serious swipe at Pentagon procurement and supply management, ordered the military services "to force more economies" in contracting. The committee's way of doing this: an over-all $400-million cut in general procurement funds. The Defense Dept. is directed to apply this saving down the line as a means of tightening up on pricing, costs, etc.

The appropriations report complains of "the seeming inability of the services to formulate reasonable and realistic plans and specifications which would allow the maximum utilization of formal competitive bidding."

The report cites cases of "profit-to-cost ratios of 24 to 41 percent" on Army Nike subcontracts, additional costs exceeding $3 million on an unspecified Air Force prime contract for fire control radar, and lower cost estimates on an unnamed Sage electronic component when bought under advertised procurement rather than negotiated contracting.

The House committee's action is just the first step in the prolonged mechanics which engulf defense budgets. Still to come: action by the House as a whole, a report from the Senate Appropriations Committee, a Senate vote, then compromise between the House and Senate versions.

Right now, the outlook is for a steep Senate increase in the military appropriation—close to $1 billion, no doubt. The final Congressional version is expected to bring this budget increase down at least 50 percent.

SHIPEMENTS OF ELECTRONIC COMPONENTS in 1959 jumped more than 30 percent over 1958 totals to a new all-time record amount. A Commerce Dept. report (BD-60-64) spells out the quantities and values of shipment by major category and breaks down the total into military and non-military use.

The report on 1959 electronic component shipments, prepared by the Defense Dept. Electronics Production Resources Agency and Commerce's BDSA Electronics Div., is available upon request from the Commerce Dept. It should be extremely useful in market programming.
NOW!

Constant output level
Constant modulation level
3 volt output into 50 ohms
Low envelope distortion

New *hp* 606A HF Signal Generator

Here at last is a compact, convenient, moderately-priced signal generator providing constant output and constant modulation level plus high output from 50 kc to 65 MC. Tedious, error-producing resetting of output level and percent modulation are eliminated.

Covering the high frequency spectrum, (which includes the 30 and 60 MC radar IF bands) the new 606A is exceptionally useful in driving bridges, antennas and filters, and measuring gain, selectivity and image rejection of receivers and IF circuits.

Output is constant within ±1 db over the full frequency range, and is adjustable from +20 dbm (3 volts rms) to —110 dbm (0.1 μV rms). No level adjustments are required during operation.

**SPECIFICATIONS**

| Frequency Range: 50 kc to 65 MC in 6 bands. |
| Frequency Accuracy: Within ±1%. |
| Frequency Calibrator: Crystal oscillator provides check points at 100 kc and 1 MC intervals accurate within 0.01% from 0° to 50° C. |
| RF Output Level: Continuously adjustable from 0.1 μv to 3 volts into a 50 ohm resistive load. Calibration is in volts and dbm (0 dbm is 1 milliwatt). |
| Output Accuracy: Within ±1 db into 50 ohm resistive load. |
| Frequency Response: Within ±1 db into 50 ohm resistive load over entire frequency range at any output level setting. |
| Output Impedance: 50 ohms, SWR less than 1:1 at 0.3 v and below. |
| Spurious Harmonic Output: Less than 3%. |
| Leakage: Negligible; permits sensitivity measurements to 0.1 μv. |
| Amplitude Modulation: Continuously adjustable from 0 to 100%. |
| Internal Modulation: 0 to 100% sinusoidal modulation at 400 cps ±5%, or 1000 cps ±5%. |
| Modulation Bandwidth: Dc to 20 kc maximum. |
| External Modulation: 0 to 100% sinusoidal modulation dc to 20 kc. |
| Envelope Distortion: Less than 3%; envelope distortion from 0 to 70% modulation at output levels of 1 volt or less. |
| Spurious FM: Less than 0.0001% or 20 cps, whichever greater. |
| Spurious AM: Hum and noise sidebands are 70 db below carrier. |
| Frequency Drift: Less than 0.003% or 5 cps, whichever greater. |
| Price: (cabinet) $1,200.00, (rack mount) $1,185.00. |

Data subject to change without notice. Prices f.o.b. factory.

Now... an Economy-size Optical Comparator
with "Big Machine" Features

Here is a fine optical inspection and measuring instrument of brand-new design. It is the first small-screen comparator to offer such BIG performance. It is equally suitable for production-line operation or job-shop work, and is extremely flexible in application.

The J&L TC-10 is of precision machine tool construction. This provides a solid base for precise inspection and measurement.

Three different table styles are available, including a fixed table for straight comparison work, a plain table, and a measuring table which gives you 6 square inches of measuring area. All measurements are read directly to .0001", without computation.

Among other things, the TC-10 is adaptable for reflection inspection. Reflected images are extremely sharp—even at high magnifications.

Other "big machine" features include Angle Measuring; Quick-Change Lens Mount; Vertical Staging; Tracing Inspection. And there's a big bonus in the 5X, 2" aperture lens, which gives inspection capacity and accuracy hitherto unattainable on a machine of this size.

GENERAL ELECTRIC SEMICONDUCTORS

Close control of temperature and humidity is as essential a part of General Electric's quality assurance procedures as the characteristic tests and other specifications. For this reason, you will find "Air-conditioned" and "humidity-controlled" the bywords in the production process. These tests are also rigidly prescribed to keep our stock (and yours) uniform.

Operate perfectly, transistors manufactured under General Electric's exclusive broad-band mounting process. Critical elements are welded in a plug of resin so that the entire device acts as a solid block resisting shock and vibration. Three years' safety in requirement of all standard stock, container and temperature: a "day-light" device.

As part of General Electric's testing procedures, transistors are to a satisfactory level, the device is mounted through the "Nose-into" test, which can detect leaks at the rate of 200 per minute. It is this high-speed test at American Standards.

GENERAL ELECTRIC DISTRIBUTOR

For on-the-spot service on General Electric Semiconductors, at factory-low prices, contact your nearest General Electric Distributor.

GENERAL ELECTRIC SEMICONDUCTOR PRODUCTS DEPARTMENT, ELECTRODE PARK, SYRACUSE, N. Y.
General Electric transistors and rectifiers have earned a reputation for reliability without equal in the industry. Superior quality is built into all G-E semiconductor products. Critical control of every step from refining the raw materials to packaging the finished product means consistently outstanding performance.

Through 1959, General Electric has manufactured over 21,000,000 transistors, of which over 30,000 were diverted for life-testing. Life test readings total 2,293,000.

Among the more than 30,000 transistors on G-E's cycle life-test racks at any time are Series 2N34 PNP germanium devices dating back to 1954. Each has clocked at least 40,000 hours, or five years of "power-on" operation without failure.

But life testing is only one of the product quality assurance procedures through which all General Electric semiconductors must pass. The average is sixteen separate tests—electrical, mechanical, thermal, and environmental, as well as life.

General Electric has also introduced a series of design improvements which have raised reliability expectations to a new peak. G.E.'s Fixed Bed Mounting, for example, almost overnight changed delicate grown-junction devices into rugged units with extreme stability and inherently higher power dissipation. One Fixed Bed Mounted Series, type 2N313A through 2N313A, can dissipate up to 500 mw without a heat sink at 25°C, providing an unusually wide safety factor.

Tightly controlled parameters, low capacitance, and low d-c to r-f current ratio are three outstanding features of General Electric's tunnel diodes, now available for the first time in production quantities at sharply reduced price.

Pioneered by General Electric, this newest member of the fast-growing family of electronic devices is smaller, simpler, and many times faster than a transistor. It takes advantage of quantum mechanical tunneling to attain unique negative capacitance and very high frequency performance.

G-E germanium tunnel diodes provide switching times of 7 milliseconds and reverse conduction time of 3 microseconds. These devices offer good temperature stability, extreme insensitivity to nuclear radiation, a closely controlled peak point current with a peak-to-noise ratio of 1 for the lowest-priced 2N1948. See your G-E Semiconductor Sales Representative for complete specifications and application data.

### Rectifiers

General Electric's record in rectifiers is outstanding—over 20,000,000 units produced, over 70,000 units life-tested (not including government types). Survival rates of 98.5%, in operating tests at maximum ratings for many thousands of hours, are not unusual.

In the medium and high-current areas, General Electric has completely eliminated soft solder joints and with them has greatly reduced the problems of thermal fatigue. This means that G-E medium- and high-current alloy rectifiers can be worked right up to maximum current and temperature ratings, even on highly cyclic loads.

In addition, all General Electric medium- and high-current rectifiers now carry transmit PIV ratings which give the user additional protection against voltage transients.

The rectifier cells shown are listed in ascending order based on forward current ratings. Maximum full load voltage drop is taken at full cycle average. Complete specifications are available through your Semiconductor Products District Sales Office or your authorized G-E Semiconductor Distributor.

#### Low Current germanium alloy cells

General Electric germanium alloy rectifiers have become the industry standard for high reliability units. They have demonstrated extreme long life under cycling with a lifetime survival rate of 95%. These units feature extremely low forward resistance, high back resistance.

![Low Current germanium alloy cells](image-url)
THE BIG A LEADS THE WAY
TO INTEGRATED COMMUNICATIONS SYSTEMS

SATELLITE RELAY SYSTEM  A reliable, worldwide network for television, facsimile, telephony and telegraphy communications will be realized in the near future through PROJECT COURIER of the Advanced Research Projects Agency and U.S. Army Research & Development Laboratories. As subcontractor to I.T. & T., Adler is responsible for engineering and manufacture of the ground stations of this earth-satellite relay. Each of these air-ground transportable stations can duplex transmit, receive and store 15 million bits of information in the 4-minute-contact with the satellite. The COURIER's pre-launching checkout system, also, was produced by Adler.

TRANSPORTABLE TROPOSPHERIC SCATTER SYSTEM  A new concept in continent-spanning tropospheric scatter communications soon will be available to the U.S. Air Force. For the first time, the full multichannel capability and reliability of a large, fixed installation will be provided in a compact, air-ground transportable package. The all-environment, 10KW, AN/MRC-85 is being designed, system integrated and manufactured by Adler under subcontract to Page Communications.

SPECTRUM-STRETCHING COMMUNICATIONS SYSTEM  Through Adler pioneering in heterodyne repeating, a wide range of UHF channels have been opened to the U.S. Army for NIKE Missile field communications. The Adler "F-Head" unit permits the basic AN/TRC-24 VHF system to be used for UHF relaying in areas where VHF spectrum congestion is a problem. Designed for plug-in use, the "F-Head" heterodynes the VHF output of the AN/TRC-24 to the usable UHF range. Adler heterodyne techniques are finding an ever-growing place in military, industrial and commercial communications.

Write for all the facts on how Adler experience can help solve your communications problems.

ENGINEERING THERMOPLASTIC MEETS SPECIAL NEEDS OF INTRICATE, PRECISION MOLDING . . .

This precision-engineered electronic component for a new IBM Data Processing System is molded of Merlon polycarbonate because it is a self-extinguishing thermoplastic that combines high dimensional stability and mechanical strength with good dielectric properties and a high heat distortion point.

If you haven't seen the facts and figures on Merlon's engineering properties, based on comparative test data studies with other thermoplastics, write for Mobay's TIB No. 41-M1. Or, for immediate technical service assistance, a letter outlining your design problem will get prompt attention.

MOBAY PRODUCTS COMPANY
Pittsburgh 5, Pennsylvania

SUBSIDIARY OF MOBAY CHEMICAL COMPANY
Reports Earnings 44% Higher

General Precision Equipment Corp., New York, announces earnings of $1,322,000 for the first quarter of this year, or 86 cents a share. This is a rise of 44 percent over the $920,000 earned in the first quarter of 1959. Sales for the first three months of this year were $55,656,921, compared with $47,035,711 a year ago. Company officials expect total 1960 sales to be in the $225-$240-million range. J. W. Murray, GPE chairman, also announced the formation of a new company, Kearfott Semiconductor, which will manufacture transistors in W. Newton, Mass.

Laboratory for Electronics, Boston, is filing with Securities and Exchange Commission to register a maximum of 100,000 shares of common stock to be offered initially to shareholders. Paine, Weber, Jackson & Curtis will head the underwriting. Company officials say they need another $2 million in new working capital to finance expansion and conduct company business at its present rate.

Ling-Altec Electronics and Temco Aircraft Corp., both of Dallas, are studying a merger proposal. If plans go through, the new entity will be called Ling-Temco. Each present Temco stockholder would receive 8 of a share in the new company, and each present Ling-Altec share would be exchanged on a one-for-one basis. The companies' combined sales last year topped $148 million.

Dynamics Corporation of America reports plans to begin issuing regular quarterly sales-earnings reports to shareholders for the first time in its history. The new policy, according to R. F. Kelley, is made feasible by the achievement of a better balance between R&D work and actual production and shipments. For the first quarter of this year, DCA recorded sales and other income of $10,072,708, compared with $6,385,418 in the first quarter of last year. Per-share earnings after taxes were 14 cents, double the 7-cent figure recorded in the same period last year.

Collins Radio, Cedar Rapids, Ia., announces formation of an Australian subsidiary. The new arm, Collins Radio Co. (Australasia) Pty, will locate in Melbourne. It will act as the sales and service unit for Australia, New Zealand and Southeast Asia. A spare parts service center and complete test facilities will be maintained.

* to be announced

No doubt your engineers take great pride in the semiconductor components they design to represent your company in the world market. And your engineers know: (1) that you must be able to produce in volume to meet the challenge of competition; (2) that it takes many months of development work and scheduling to get a semiconductor processing program into high gear.

Now a question. What happens if (in spite of this knowledge and the careful planning it inspires) your company's source for graphite parts suddenly vanishes from the scene, or for some not too mysterious reason simply cannot meet the accelerated volume requirements of a successful semiconductor program? The answer.

You're in a very awkward position. And your engineers have nothing much to show for their efforts except some lingering pride in a design they know could have been a winner.

Scary story? Yes. But it could happen to you. It has to others. It's a very good reason why you (and your engineers) should insist on a competent, experienced, insured source for graphite parts. Here is that kind of source.
Plan For Uniform Performance

Low Power Factor and Constant Capacity Assured by Dow Corning Silicone Fluids

Here's an example of value engineering with silicone fluids:

The Filtron Co., Inc., of Flushing, N.Y., manufactures RF interference filters and capacitors for both military and commercial use. To assure an almost constant capacitance vs temperature relationship for their specialty capacitors . . . and the lowest possible power factor for their RF interference filters . . . Filtron engineers impregnate them with Dow Corning silicone fluids.

Silicone fluids are, in themselves, excellent dielectrics. In capacitors and RF filters such as these, silicone fluids boost the performance of the paper dielectric . . . substantially increase permissible operating temperatures, decrease electrical losses. Highly stable to changing environments, silicones show little drift in electrical or physical properties over a broad range of temperature and frequency conditions. They add greatly to reliability . . . often eliminate costly compensating circuits.

Dielectric-Coolants . . . Silicone fluids also make highly effective heat transfer media. Because of their relatively constant viscosity, their pumping rate does not vary appreciably at differing temperatures. They're nonoxidizing, nongumming . . . can be sealed in for the life of the equipment. Electric grade fluids may be cycled directly over operating assemblies.

Your nearest Dow Corning office is the number one source for information and technical service on silicones.
... engineer for value with silicones

Solventless Resin Fills A Void

This servo motor, made by G-M Laboratories, Inc., Chicago, must withstand high humidity and high temperatures in operation. On analyzing the requirements of size, weight and reliability, engineers at G-M Laboratories concluded that a silicone insulation system would permit the best design, so they impregnated the stator under vacuum with Dow Corning solventless silicone resin. This moisture-proof, heat-resistant material fills the coil interstices and sets up to a solid, bubble-free mass. It protects against vibration, oxidation, corona and moisture... provides good heat transfer. Investigate Dow Corning solventless silicone resins for use as rigid potting, filling, impregnating or encapsulating materials. They're radiation resistant... can be used with inorganic fillers.

CIRCLE 290 ON READER SERVICE CARD

Soften Shock With Silastic RTV

This transistorized oscillator, produced by Delta-f, Inc., Geneva, Illinois, is designed for use in airborne and transportable communications equipment. To protect against shock, Delta-f engineers use a flowed-on blanket of Silastic® RTV. It supplies needed cushioning, and is unaffected by the built-in heating element. Silastic RTV can withstand temperatures up to 260 C, down to −70 on the cold side. In addition, it resists moisture, oxidation, and other adverse conditions. Silastic RTV is the Dow Corning fluid silicone rubber that vulcanizes at room temperature. Easy to use, it can be applied by dipping, pouring or with a caulking gun. When used as a potting material, it flows into place, filling all voids... sets up to form silicone rubber with excellent dielectric properties.

CIRCLE 291 ON READER SERVICE CARD

For Maximum Security: Silicone-Glass

Ground approach radar must provide the ultimate in reliability. That's why Gilfillan Brothers, Inc., of Los Angeles, use silicone-glass laminates in their Quadradar sets which are designed to provide vital flight information that facilitates ground controlled approach and landing of high speed aircraft. Silicone laminates are specified because they have uniform dielectric properties under climatic and atmospheric conditions. Little affected by moisture, silicone-glass terminal boards prevent recurrent arcing even at high voltage and high humidity... provide low loss factor and low attenuation at RF frequencies. In addition, silicone laminates are strong and resist creep under pressure of fasteners; and, when needed, their heat resistance is exceptional... up to 250 C continuous for years on end.

CIRCLE 291 ON READER SERVICE CARD
MARKET RESEARCH

Slip Ring Sales Rise 25% Yearly

SLIP RING ASSEMBLIES are becoming a major electronics industry component market, says George Pandapas, president of Electro-Tec Corp., a major producer of precision slip rings.

Essentially electrical joints, slip rings are used wherever electrical signals must be transmitted from a rotary object to a stationary one. Major equipment applications are in gyro for missiles, aircraft and spacecraft and in radar antennas. Pandapas estimates 1960 sales of precision, high-performance slip rings will total $10 million. Estimate excludes slip rings manufactured for captive markets (currently worth about $10 million annually), and those made for use with synchros and resolvers.

Sales have been gaining at a 25-percent annual rate for several years, he says. But the annual rate of gain will probably jump to 50 percent over the next five years, Pandapas adds.

Extent of the movement of aircraft firms into electronics was recently highlighted by George M. Bunker, chairman of The Martin Co., in a talk before the New York Society of Security Analysts. Of 7,500 engineers employed by Martin, 3,500 are in electronics. Traditionally an old-line airplane manufacturer, Martin has become a manufacturer of diversified weapon systems, many of which are electronic and none of which includes a new airplane design. Change came about because of the capabilities needed to build missile systems and their guidance, control, ground and support equipment—all largely electronic.

Military suppliers must plan on increasing sales in future years and learn how to perform research and development contracts profitably in order to maintain current profits, Bunker said. It now appears that more and more of the available defense industry business will be in low-profit-margin research and development work. Eighty percent of Martin’s present business is in cost-plus-fixed-fee contracts.

Bunker stressed the value of reports on hearings of the House Subcommittee on Appropriations as one of the best sources of information on military markets and developments.

There was no reasonable basis for thinking the Titan program would be cancelled, he said, “and if commentators had paid more attention to committee testimony than to flight tests this situation would have been obvious.”

Lt. Gen. Bernard A. Schriever, head of Air Research and Development Command, recently testified: “When people talk about canceling out the Titan, they simply are not familiar with all the facts and problems that go into bringing missiles into the operational inventory. To cancel out today would mean that we would have approximately one-third less missiles in our inventory in this critical time period than we now have programmed.”

30 db gain in 200 mc RF amplifier

...with TI 2N1141 series germanium mesa transistors

Exceptionally high ac beta TI 2N1141 germanium mesa transistors provide 30 db gain — with 16 mc bandwidth — in a 200 mc RF amplifier. Ideal for your high frequency amplifiers and power oscillators, 2N1141 series diffused base transistors give you ... maximum dissipation to 750 mw . . . voltage ratings to 35v at 100 |u|A . . . 750 mc alpha cutoff. These devices are backed by more than 3,500,000 unit hours of life test reliability data . . . see curves below.

UNIT TYPE 2N1142: I(CB) AND hFE VS HOURS OF STORAGE AT +100°C

TEST LEGEND: Sample Size: 1000 units • Test Condition: Storage at +100°C • I(CB) Measured at: VCE = —20v, I(E) = 0 • hFE Measured at: VCE = —6v, I(C) = —10ma

Contact your nearest TI distributor or sales office for immediate delivery.

DESIGN LEADERSHIP IN QUALITY GERMANIUM TRANSISTORS

TEXAS INSTRUMENTS INCORPORATED SEMICONDUCTOR-COMPONENTS DIVISION 13500 N. CENTRAL EXPRESSWAY POST OFFICE BOX 312 - DALLAS, TEXAS
recognized leadership in the design and manufacture of slip ring assemblies.

The country's leading producers of electrical and electronic equipment look to Makepeace for the design and manufacture of slip ring assemblies.

Slip ring design for particular applications depends upon the various electrical and mechanical factors involved. Thus, Makepeace has developed many special alloys and combination of alloys to meet a wide range of requirements. Our engineers and metallurgists are thoroughly qualified in this specialized field and will be pleased to make recommendations on your particular problem.

Complete facilities are available for the manufacture of slip ring assemblies ranging in diameter from 1" to 48" and larger—for General Purpose, Radio Frequency and Video Ring Circuits, High Speed Instrumentation, High Voltage Ring Circuits and Power Pulse Slip Rings. A slip ring data file is available—write for your copy.

fine wire, thin foils, ribbon and tubing in noble metals and their alloys, for all applications.

The unique combination of properties of the noble metals continually recommend them for industrial applications. Our modern melting, wire drawing, rolling and heat treating equipment coupled with long experience in the field is at your service for production of standard and special items.

WIREs: Bare drawn wire of ductile materials down to .004"—High temperature thermocouple wires—High temperature furnace windings—Potentiometer and Resistance wires—Platinum clad tungsten wire.

FLoILS: In platinum, palladium and gold down to .0001"—In iridium and rhodium as thin as .001".

TUBING: Seamless in platinum, palladium, gold and their alloys. Sizes from .018" with .004" wall up to 1 1/2" with .042" wall.

For complete information write for our leaflets, "Fine Wire, Foils, Ribbons" and "Noble Metal Thermocouple Wire".

BAKER PLATINUM DIVISION • 113 ASTOR STREET
NEWARK, N. J.
a simplified mirror-bright silver plating process for electrical and electronic components

Here is the most efficient, simple procedure to protect electrical electronic and lamp components with a mirror-bright silver finish—through a complete range from flash to heavy deposit. The procedure is easy, economical and non-critical—with little or no polishing required. Silva-Brite is a clear, water-white solution, enabling the operator to observe work as it is being plated. Uniformly good results are attained with current densities ranging from 10 to 40 amperes per square foot. Normal room temperature operation minimizes fumes and tendency toward bath decomposition. Send for descriptive data together with detailed plating procedures.

for low cost purification and drying of hydrogen and other gases

The Deoxo Catalytic Purifier is combined with an extremely efficient automatically operated drying unit to provide oxygen-free hydrogen that is ideally pure and dry. The combined units are identified as the Deoxo Dual Puridryer. It supplies hydrogen with less than one part oxygen per million—dried to a dew point of -100°F. No inert gas purging is needed. The Deoxo Dual Puridryer can also be used with other gases such as: Nitrogen, Argon, Helium and saturated hydrocarbons, with equally fine performance. Write for descriptive literature.
CONQUERING SPACE YOUR PROBLEM?

The NEW \( \frac{1}{2} \) CIC FILM POT IS THE ANSWER

LINEARITY 0.2\% • INFINITE RESOLUTION • LONG LIFE

This subminiature film pot has much greater accuracy than comparable wire-wound types and features the reliability inherent in film pots. Now you can meet tight space requirements without sacrificing accuracy. Send us your specifications.

MAY 13, 1960 • electronics
The Offner Type RD Dynograph provides the same performance, the same convenience as the Type RC, (the Type R without pre-amplifiers). Economies in design were made possible by eliminating circuit components necessary only when preamplifiers are employed.

In the Type RD each amplifier is completely replaceable; only the power supply is common.

The Type 473 Amplifiers are all-transistor in construction, and provide advantages of high reliability and instant operation with no stabilizing warm-up. Sensitivity is 10 MV per cm. to 100 volts per cm., with a zero drift of less than 0.2 MV per hour at highest sensitivity.

The Type RD Dynograph assemblies are ideal for systems applications, telemetering, and other uses not requiring the greater versatility and sensitivity of the Type R. It is available in a variety of mountings, including the BMR rack, or for mounting in standard racks.

**SPECIFICATIONS**

- **Sensitivity**: 10 MV per cm. to 100 volts per cm.
- **Drift**: 0.2 MV per hour at max. sensitivity.
- **Frequency Response**: To beyond 200 cps, ± 10%.
- **Zero Suppression**: 40 cm., plus and minus.
- **Recording Media**: Ink or electric curvilinear; heat or electric rectilinear. Recording media interchangeable.
- **Number of Channels**: One to eight standard with Type 504A rack-mounted paper drive (illustrated). Up to 24 on other mountings.

1. From low resistance source at normal ambient.
2. Ink or electric recording. Heat sensitive limited by capability of medium.

The Offner Type RD is available in a variety of mountings, including the BMR rack. The Type R (illustrated above in the BMR rack) should be specified where microvolt sensitivity and greatest versatility are required.
Our Defense Against Attack From Space

By JOHN F. MASON,
Associate Editor

DEFENSE against destruction by nuclear bombs carried by ballistic missiles, reentry satellites, or other vehicles from outer space, is considered by many to be the most urgent need facing the U. S. today.

Solution to this problem is probably the greatest challenge, to date, to the imagination and ingenuity of the electronics industry.

Administering these creative efforts is the task of a portion of the Defense Department's Advanced Projects Agency (ARPA) known as Project Defender.

Participants in the effort are all three military services, other government agencies, universities and industry.

The work consists of a mountain of contracts—study, R&D, and hardware. At first glance, few of the contracts appear to have much relation to the others. This seeming discrepancy is due to the vast number of areas in which solutions, or partial solutions, might be found.

(For a listing of major contracts see ELECTRONICS, p 42, Feb. 26.)

Funds appropriated for fiscal year 1960 amount to $106 million; requested for 1961, $110 million more. Funding for succeeding years will be bigger since study contracts will turn into systems contracts requiring more engineering and hardware.

Common denominator of Defender contracts, present and future, is the attempt to come up with a way to nullify an attack by nuclear-armed vehicles entering the earth's atmosphere from outer space.

There are several theoretical ways to do this:

1. Detonate the bomb prematurely before it's close enough to do any damage.

2. Convert the nuclear mixture, somewhere along the vehicle's route, to a harmless “bucket of sand” so that the impact damage will be no greater than a clean cut hole in the ground.

3. Send the missile back into outer space intact by use of an anti-gravity device.

4. Get rid of the whole thing—vehicle, payload and all—by using an antimatter projector which would turn it into its opposite: Nothing.

Though application of concepts (3) and (4) belong at present to blue sky thinking, basic research is being performed in these fields. The outcome may one day be as significant as the basic research that resulted in the atomic bomb.

ARPA's Approach

ARPA is actively concerned with detection and interception techniques beyond present conventional concepts. To keep ahead of the game, new concepts must be evaluated. “Far-out” ideas are not dignified into projects but they are given a hearing by ARPA physicists.

One of the first problems is: In which of the missile's three trajectory phases can it best be attacked—boost phase, mid-course, or terminal? Secondly, how can it be attacked in each stage—by vehicle or by other means?

Boost Phase

Convair has just completed a Defender contract to study the problems involved in detecting and killing a missile during its boost phase.

This is a vulnerable period for a missile. All its subsystems are in operation; guidance—which might be jammed; propulsion—the fuel supply might be punctured; controls—damaged or misdirected; payload—predetonated.

Requirements for killing a missile during its powered phase include: immediate detection and interception while the missile is over enemy territory. One method might involve a detection satellite that also carries kill capabilities—either electromagnetic jamming or the actual launching of an intercept missile. Detection might be achieved by a long range ionospheric scatter sys-
tem like Navy's Teepee, based a
safe distance away, but kill would
probably have to originate over the
enemy country.

ARPA plans to spend $2 million
in 1961 for studies on guidance and
control features for intercept mis-
siles launched from the ground, air-
craft or space vehicles.

Of all the phases of the trajec-
tory, the boost phase is probably
the one with which missile engi-
neers have had the most experience.
Even failures at the U. S. missile
ranges have at least gone through a
part, or all, of this phase. Good data
during powered flight are available
from telemetry, radar, infrared and
optical measurements and from
first-hand examination of recovered
vehicles.

Part of a $57-million request for
missile range measurement equip-
ment will be used to study boost-
phase missile characteristics. In
the Atlantic Missile Range, De-
defender operates two converted
mariner ships, laden with electronic
gear, and a number of aircraft car-
rying infrared equipment.

Mid-Course

In some ways the mid-course
phase offers advantages to a de-
defender. The enemy no longer has
control over the missile; guidance
and power are both off. The missile
is following a predictable trajectory
and is not yet affected by reentry
into the earth's atmosphere.

The problems, however, are nu-
meros. Distance to point of inter-
cept is formidable. Speed of the
intercept missile would have to be
far greater than that of the target.
In case of a salvo of 100 enemy mis-
siles, how many intercept missiles
and what kind of omniscient guid-
ance would be used to keep all the
intercept missiles from attacking
the same target, letting the other
99 get by? The problem suggests
the nightmarishly complicated solu-
tion of sending 100 intercept mis-
siles up, with no preset guidance, to
wait, choose a target, and attack.

A far more comprehensive, and
therefore comfortable, solution
would be erecting a screen to de-
tonate or nullify all warheads passing
through it. Such a screen could pos-
sibly take the shape of a ground-
based particle accelerator.

ARPA is studying the Argus ef-
flect, the release of chemicals at
high altitude and the creation of
artificial electron clouds and lum-
nescence. ARPA is asking for $10
million for this kind of work under
"Physics."

ARPA plans to spend $9 million
more in 1961 to study new ways to
kill missiles and satellites.

Precise knowledge of missile
characteristics during the mid-
course, coasting phase is more dif-
cult to come by than during the
powered phase. Far fewer missiles
at the test range have gone this far.
Distance makes precise monitoring
more difficult. And the physical con-
ditions in outer space are still rela-
tively unknown quantities.

ARPA has an active radar pro-
gram to develop long-range, high-
capacity, high-resolution radars
that are significantly beyond the ca-
pability of existing radars. This
is particularly necessary, ARPA
stresses, for midcourse studies.

To date, the program has accom-
plished, ARPA says: initiation of
development of h-f multiple-beam
radar, called Pincushion, by Ray-
theon; continuation of development
of a multielement, electron-
ically-scanned radar (ESAR) by
Bendix; continuation of multi-static
radar development (ORDIR), by
Columbia University; initiation of
development of a super-power mi-
crowave tube; continuation of re-
search in high-power components,
radar receiving techniques, signal
processing techniques and various
others.

Two new radars, Raytheon's Pin-
cushion and an RCA tracking radar,
will be installed on Kwajalein to
study midcourse missile character-
istics of test flights launched in the
Pacific.

Terminal Phase

Major effort to date has gone into
defense against missiles during
their terminal phase. Nike-Zeus,
antimissile missile still in the R&D
stage, is the product of this en-
deavor.

Defender's objective, however, is
to come up with concepts beyond the
capabilities of a Nike-Zeus-type
system.

Problems in the terminal phase
are lack of time and target dis-
crimination.

ARPA is requesting $4 million
for research on target discrimina-
tion (decoy sorting) and counter-
measures (the enemy will want to
jam ground radars and guidance of
intercept vehicles).
When it comes to cost estimating...

...there's nothing like a handy white-printer to cut preparation time of cost estimates, according to the Stackpole Carbon Company, St. Mary's, Pa. The company's Supervisor of Cost Estimating has just written us a letter on the subject which we pass on to you verbatim. "Our estimates are made in pencil on printed translucent vellum in pad form. These are reproduced on specially cut and punched Ozalid copy paper. Originals carry only basic information that has to remain constant. And from the originals we produce duplicate originals on Ozalid sepia line intermediate paper (402 IT) as required, and these are used until the basic information is obsolete. To revise a cost, it is only necessary to add current rates and extend. With this simple Ozalid method we have eliminated typing, proofreading, and copying errors."

The Supervisor goes on to say that Stackpole uses Ozalid copying in many other areas of its business because of convenience and economy. Perhaps we'll be able to tell you about these uses in a future Newsletter.

Here's what 100 usable feet per minute can do for you

Speed up your production? Of course! But that's only the beginning. Look at it this way. One Printmaster 1000 working at a usable 100 feet per minute matches the output of several smaller, slower machines but takes up less valuable floor space while handling widths up to 54 inches! You save on production time and costs due to higher working speeds! And the Printmaster 1000 is probably the toughest, most durable unit ever produced. This means even greater savings in downtime and service charges. Our first recommendation for any shop having heavy work loads is this 100-foot champ... the Printmaster 1000.

Need low-cost color in a hurry?

Four-color, three-color, or even two-color for that matter... no problem; Ozalid's Viewfilms provide the perfect low-cost answer.

Suppose we want to produce a performance chart in which each factor is a different color.

It's a snap. Just take translucent paper and draw the desired curve or dotted line (as the case may be) on the sheet.

Next, run the master through your Ozalid machine together with an Ozalid Viewfilm of the proper color. Want to add more material in a different color? Just prepare another master, select a different colored film, and run them as you did the first pair. When you're all through, overlay the films in sequence and tape them into register. Your result is a composite color chart that's very dramatic... very convincing!

This is just one illustration to start your mental salivary glands working. We are sure that you can find uses we haven't even dreamed of, once you get going. And if you discover any new applications for this best of all possible color worlds, tell us about them so we can spread the good news to others.
Easy to operate, highly stable, wide range

Precision oscillators perform a wide variety of audio, video, and low frequency tests. They offer the outstanding advantages of flexibility and broad usefulness at moderate cost. Employing the i pioneered RC resistance capacity circuit, the units combine accuracy and reliability with ease of operation and minimum adjustment.

202A FUNCTION GENERATOR—Down to 0.008 cps; transient-free!

Uses: Electrical simulation of mechanical phenomena, vibration studies, servo research and testing, medical research, geophysical problems, subsonic and audio testing.

Advantages: No switching transients, continuously variable 0.008 to 1,200 cps range, 30 v output peak-to-peak constant, hum less than 0.05%, square, triangular or electronically synthesized sine waves, 1% stability, 0.2 db response, less than 1% distortion (sine waves) on all but x 100 range.

Price: $525.00 (cabinet model), $510.00 (rack mount).

650A TEST OSCILLATOR—Flat within 1 db, 10 cps to 10 MC!

Uses: Testing TV amplifiers or wide-band systems, measuring filter transmission characteristics and tuned circuit response, determining receiver alignment, making telephone carrier and bridge measurements.

Advantages: No zero set, no adjustments during operation, output voltage range 30 u to 3 v, less than 1% distortion, 20 cps to 100 KC; less than 2%, 100 KC to 1 MC; approx. 5% at 10 MC. Hum less than 0.5%, output voltage attenuator, self-contained voltmeter, 2% to 3% stability.

Price: $490.00 (cabinet model), $475.00 (rack mount).

205AG AUDIO SIGNAL GENERATOR—Six instruments in one; 20 cps to 20 KC!

Uses: Measure amplifier gain and network frequency response, measure broadcast transmitter audio and loudspeaker response, drive bridges, use in production testing or as precision source for voltages. Monitors oscillator output, measures output of device under test.

Advantages: Self-contained instrument, no auxiliary equipment needed. 5 watts output, ± 1 db response, less than 1% distortion, hum more than 60 db down, no zero setting, output and input meters read v and dbm; four output impedances.

Price: $500.00 (cabinet model), $485.00 (rack mount).

206A AUDIO SIGNAL GENERATOR—Less than 0.1% distortion; 20 cps to 20 KC!

Uses: Convenient, precision audio voltage source; checks FM transmitter response, makes high quality, high fidelity amplifier tests, transmission measurements.

Advantages: Continuously variable audio frequency voltage, (output 15 dbm) 0.2 db response, hum 75 db down, 2% frequency accuracy, less than 0.1% distortion. 111 db attenuator with 0.1 db steps.

Price: $750.00 (cabinet model), $735.00 (rack mount).

Data subject to change without notice. Prices f.o.b. factory.

Engineering hints from Carborundum

Correct techniques simplify production of KOVAR® Alloy drawn shapes

KOVAR is an iron-nickel-cobalt alloy with thermal expansion characteristics essentially matching those of several hard glasses. It is the ideal material for making high-quality drawn shapes required for vacuum- or pressure-tight glass-to-metal seals in equipment such as electron tubes and semi-conductors.

KOVAR has deep drawing qualities similar to cold-rolled steel. Satisfactory results are assured by observing a few simple precautions:

1. On the initial draw, punch radius should be a minimum of four times the material thickness. Reduce successively on re-draws.
2. Inside radii at the corners on the final draw should be not less than the thickness of the metal.
3. Sharper radii, if absolutely essential, should be produced by a subsequent coining operation.
4. Hold-down pressures in drawing should be kept to a minimum to insure metal flow from the outside rather than stretching.

For permanent vacuum and pressure-tight sealing . . . count on

CARBORUNDUM®

Obviously, to prolong tool life and simplify production, maximum permissible tolerances should be allowed. More detailed information on deep drawing of KOVAR alloy is supplied in Technical Data Bulletin 100 EB11.

Carborundum maintains large stocks of KOVAR alloy in a wide variety of sizes and forms. This alloy can be welded, brazed, soldered and plated with other metals. It can be either oxide bonded to hard glass or brazed to metallized-ceramic insulators. Technical service is available to help you solve processing and application problems. Contact The Carborundum Company, Refractories Division, Dept. E-50, Latrobe Plant, Latrobe, Pa.

40 CIRCLE 40 ON READER SERVICE CARD

CIRCLE 41 ON READER SERVICE CARD
The complete integrated Model FIM includes:

1. A monitoring unit. Meter indicates average, peak or quasi-peak value of r-f signals. Outputs for video, audio and recorder.
2. R-F Plug In Tuning Units. Four units cover the frequency range 1000 to 10,000 mc. UNI-DIAL tuning control tunes both the receiver and internal signal calibrator.
3. Calibrated Antenna System complete with tripod and a calibrated omni-directional Broadband antenna or a separate directional antenna to match each R-F tuning unit.

Use this precision instrument for antenna pattern and shielding analysis, r-f power and voltage measurements, determination of field intensity, signal propagation patterns and other microwave parameters.

Determines absolute level of radiation, leakage and interference by comparison with an internally generated CW signal. Also measures signal susceptibility.

MAIL THIS CARD for specifications. Ask your nearest Polarad representative (in the Yellow Pages) for a copy of "Notes on Microwave Measurements."

New from Polarad...

PRECISION NOISE GENERATOR

- 1 kc to 500 mc
- 1 to 20 db, adjustable
- 0.25 db output accuracy
- Long-life, low-maintenance noise tubes
- Stable output

Noise output constant over entire frequency range. Maintains set level into any terminating impedance, 50 to 10,000 ohms.

Production line noise figure measurements, made rapidly and accurately with Polarad Model N-1.

The Polarad Model N-1 is a small, compact, portable noise generator with easy-to-operate controls. The Model N-1 (digitized variable output level controls — 0 to 20 db. Calibrated 1 db steps — fine vernier between each step) is entirely self-contained, including power supplies. Use it for direct noise figure measurements of vacuum tube or transistor amplifiers, receivers and oscillators.
MIL-TYPE SEMICONDUCTORS CREATE NEW DESIGN FREEDOM

Broad Bendix line meets both electrical and environmental military specs.

Here, in Bendix* Power Transistors 2N297A, 2N331, 2N1011, and 2N1120, and Bendix* Power Rectifiers 1N1614, 1N1615, and 1N1616, is a versatile line completely designed to meet military specifications. This combination —most extensive series of its type— permits unusual design latitude on military equipment applications. All units feature outstanding ruggedness and reliability to meet both electrical and environmental conditions.

The four transistors are especially suited to high-current switching, audio amplification, small motor and servo driver applications. The three rectifiers, with their low forward drop and low reverse leakage current, are ideal for magnetic amplifier and DC blocking circuits, in addition to power rectification.

Write today for NEW BENDIX SEMICONDUCTOR CATALOG on our complete line of power transistors and power rectifiers. Bendix offers engineers many challenging opportunities in semiconductors. Write Personnel Manager for full details.

SELF-POWERED PORTABLES, more color sets and additional remote control models are the major focal points of this season's television receiver market.

Most manufacturers say they have no present plans to introduce a battery-operated portable this year. ELECTRONICS learns, however, that at least one major company plans to introduce a self-powered portable three days from today.

**Color**

Expectations of increased sales of color receivers are sparked by RCA's recent reports that their sales in this line are up 40 percent for the first quarter of 1960 as compared with the same period a year ago. The company adds that inventories at almost all distribution points are low.

Packard-Bell and Admiral are also reporting increased sales of color sets. P-B president, Robert Bell, estimates last year's industry-wide sale of color receivers to be more than $50 million. He anticipates sales closer to $60 million by the end of this year. (See p 24, ELECTRONICS, Apr. 22)

If other firms are planning to come out with color sets, they are not speaking until later this month or early June when most new-line presentations are scheduled.

RCA plans to increase its color set output this year by setting up a second production facility at its Bloomington, Ind. plant. Also in the works are plans to double color picture tube output. In addition, the corporation's broadcasting facilities will be making more color programming available with increases ranging from two to five hours a week on most stations.

From all indications, there will be no appreciable alterations in present prices of color sets. Consumers will see tags ranging from about $495 to $1,100. There may, however, be some drop in service contract prices according to RCA. These now run at about $70 for the first year, $120 for the second. Set sizes will continue at the 21 and 23-in. picture tubes.

**Black-and-White**

The 19-in. set is expected to attract a good portion of the consumer market for monochrome according to most manufacturers. Virtually all brand names will soon be available in this size. Philco's new line will include three 19-in. models as well as the 17, 21 and 24-in. sizes. New engineering features in the Philadelphia company's receivers will show emphasis on top-mounted components aimed at keeping set operating temperatures down.
Magnavox is planning to introduce 19 and 23-in. sets in its new line.

The Admiral line includes two 19-in. console models and five portables. These units are wide-angle 19-in. receivers.

Bonded Tubes

Some controversy appears to be shaping up as to the merits of bonded or unbonded picture tubes. The bonded tubes have a glass safety panel bonded directly to the tube faceplate. Sylvania, which worked out much of the manufacturing process of bonded tubes along with Corning Glass, plans to stress the glare reduction, elimination of dead space and maintenance features of the tubes. In addition, the company points to the increased safety against implosion damage.

Other manufacturers appear to be taking sides on the issue. Some have rejected the bonded tubes as being too expensive as far as replacement goes; one setmaker commented on static charge buildup attracting dust.

More prudent than flat rejection perhaps, is the attitude of a third body of tv men who will introduce models next month having both bonded and unbonded picture tubes.

Remote Tuning

Once in the luxury or gadget class, the remote tuner this year will be available in a wide variety of sets ranging from the low-priced portables to the expensive “home entertainment centers.” Most manufacturers told ELECTRONICS the percentage of their set sales with remote tuning ranged in the high teens, although 30 percent of some lines are so equipped.

General Electric, planning more new models in the higher style category, says a greater percentage of GE sets than last year will be equipped for remote. Westinghouse, going along with predictions that the next season will see more emphasis on furniture styling,anticipates remote tuning will even extend to hi-fi and other audio equipment.

Along with technical upgrading, Motorola's new line will stress styling, although the amount of remote-tuned production will remain about the same number as 1959.

Leading manufacturers of hermetically sealed components have installed RADIFLO and proven it to be the most sensitive, fastest and economical method of leak detection available for mass production.

100 TIMES MORE SENSITIVE — Components can be tested as high as 10^-12 cc/sec. Super-sensitive RADIFLO reveals microscopic imperfections often undetected by less critical test methods.

TESTS NON-DESTRUCTIVELY — Rejected components need not be scrapped. The RADIFLO test method allows less-than-perfect components to be used in non-critical applications.

CAN BE PROGRAMMED AND AUTOMATED — Automatic programming feature permits modern automated mass production inspection of entire output, with immense savings in production time and labor.

ELIMINATES HUMAN ERROR — Components under test by RADIFLO are subjected to inert, radioactive gas, under pressure. During a “soaking” time the gas is forced into all existing leaks in the units. Then an air wash removes radioactive material from external surfaces. Each component is then placed in a scintillation counter for “go-no-go” inspection. A pre-selected acceptance leak rate allows non-technical workers to perform the test without error.

These leading manufacturers are among the many RADIFLO users:

SYLVANIA ELECTRIC PRODUCTS, INC.  U. S. ARMY ORDNANCE, Frankford Arsenal
GENERAL ELECTRIC COMPANY  EITEL-McCULLOCH, INC.
Syracuse, N.Y. and Waynesboro, Va.  U. S. ARMY CHEMICAL CORPS,
BULOVA WATCH COMPANY  Research and Development Command
HUGHES AIRCRAFT COMPANY  POTTER & BRUMFIELD, INC.
Tucson, Ariz. and Middletown, Pa.  FAIRCHILD SEMICONDUCTOR CORP.
WESTERN ELECTRIC COMPANY  ALLEN-BRADLEY COMPANY
ELGIN NATIONAL WATCH COMPANY  ARMY BALLISTIC MISSILE AGENCY
NIPPON ELECTRIC COMPANY

Let us help with your component leak problems. Write for complete details of automatic RADIFLO testing equipment. Manufacturers with limited production volume will be interested in RADIFLO TESTING SERVICE — now available at low cost on the east and west coasts.

"Mullard" is the trade mark of Mullard Ltd.
Single conductors or any number of pairs...for coaxial and control applications. As a “specialist in specials” Chester concentrates on meeting the increasing demands of both military and commercial electronics for plastic insulated wire and cable – particularly coaxial cables and multi-conductor constructions. Typical types are shown here. All Chester products may be varied in conducting, insulating, jacketing, shielding or armoring materials to meet your particular needs.

**RG TYPE COAXIAL CABLES**
Chester RG Type Coaxial Cables are made in both military and non-military versions, single or multi-conductor. Miniature designs are available in a choice of foam and solid polyethylene or in Teflon insulations, and in variations which include double shielding with polyethylene separator and jacket for TV systems or other low loss, all weather, signal transmission applications. Military types meet MIL-C-17 and all other applicable government specifications.

**MULTI-CONDUCTOR CABLES**
Chester is the recognized leader in the manufacture of multiple-conductor cables for computers and related electronic equipment. These cables can be supplied to your design—ranging in size from miniature to large diameters, shielded or unshielded, in a wide selection of thermoplastic insulating and jacketing materials. Any combination of appliance wire, hook-up wire and military approved wires, as well as coaxial cables and shielded conductors can be grouped to meet your specific needs. Send us your requirements for prompt engineering cooperation, and price quotation.

Complete data on Chester's full line of wires and cables for military and commercial electronic service available on request. Ask for Bulletin No. ELT-1.
—here are design parameters uniquely defined

Note how comprehensively D-B parameters cover all requirements of a standing wave detector.

D-B units are designed for unprecedented accuracy, repeatability, and operator convenience. They’re built with high-precision parts, under close quality control. Attractively styled and fully guaranteed, they have achieved a tremendous acceptance by the industry.

**Interchangeability with precision.** Any D-B unit will handle adjacent frequency bands by using a different size waveguide block and probe. You can make the change in 30 seconds, with no loss whatever in alignment accuracy.

**Complete range of sizes**—10 models cover from 5.85 KMC to 140 KMC—or you can purchase interchangeable blocks and probes to extend the range of any model, at a saving.

**Uniformity of waveguide surfaces.** D-B provides a high internal surface uniformity by precision machining its millimeter waveguides, and using carefully selected precision waveguide for lower-frequency units. This construction insures a uniform path for measured waves, thus minimizing residual VSWR.

**Slot excitation** is negligible, resulting in minimum RF leakage—another reason why residual VSWR is very low.

**Probe impedance** is properly matched to the waveguide. Uniform probe penetration is provided by a fast, convenient slope adjustment, made in a few minutes.

**Adequate probe travel** (≥ 1½ λe) available at all frequencies. Operator can read at least 3 maxima and 3 minima of VSWR.

**Efficient mechanical translation.** D-B mechanism functions with exceptional smoothness, giving the unit a definite instrument “feel.” Five point kinematic carriage suspension insures excellent linearity of probe motion.

**Vernier readout** on knob periphery permits reading of probe travel to .01mm without mounting of costly accessories.

**Continuously variable** drive ratio changes carriage travel from “vernier” to “fast”—a time saver during rapid measurements.

**Direct phase readout.** Phase shift may be measured accurately on the calibrated knob, which reads percentage of 180° directly.

For complete data, see your D-B Catalogue, or request folder DB-825.
German Electronics Comes of Age

HANOVER, GERMANY (McGraw-Hill World News)—The 1960 German Industries Fair at Hanover, Germany, showed that in western Europe as a whole and Germany in particular electronics is rapidly assuming the status of a major industry and, to meet the high technological requirements of the age, is becoming one of the most vital industries.

Prohibited until 1952 from participating in electronics in any form, Germany has marked its re-entry with two major developments either of which could revolutionize the industry. Siemens together with U. S. Westinghouse has devised a method to produce what is claimed to be the world's purest silicon; and Wacker Chemie of Munich late last year introduced a continuous process for pure crystallized silicon which can be used directly for transistor production.

Paralleling U. S. trends, small-size transistors are today being constructed to give added strength, better reliability, and lower cost. Applications at higher frequencies are being successfully tried out.

Over the next few years, production and use of electronic equipment will advance rapidly, and both vacuum tubes and semiconductors will occupy important roles in the expansion. German tube manufacturers (who mostly also manufacture semiconductor devices) are concentrating their development work on design ruggedness plus compact construction. Though a certain amount of research work has gone into ceramics as a basis for tube design, German manufacturers are presently playing the wait and see game before following the U. S. lead.

Though accurate figures are not presently available, opinion is that upwards of 10 million transistors were produced in Western Germany in 1959. Forecast for 1962 is 70 million. About 12 million semiconductor diodes were manufactured through 1959. Through this period, sales of electron tubes (including tv tubes), transistors and semiconductor diodes reached about $100 million compared to sales of $83 million in 1958.

Hit sorely by the acute labor shortage, the West German electronics industry has invested heavily in equipment and plant to step up production. Investment has been so effective that consumer goods predominantly utilizing electronic devices of one kind or another have recently been heavily reduced in price. As an example, at the beginning of the year radio and tv tube prices were cut 20 percent.

New technically improved tv sets are about eight to ten percent cheaper than last year's models and radio prices have gone down by six to eight percent. At the same time, prices for last year's models were reduced by up to 15-20 percent.

New tv sets feature uhf tuners for the second tv program scheduled to start next year. Other innovations are automatic controls adjusting voltage fluctuations as standard equipment for medium-priced sets and better serviceability: Chassis can be flipped out easily and the printed circuits are marked with position numbers of resistors and capacitors.

In radios, general trend is towards more wavelengths and smaller size. All new radios are equipped with transistors. They range from a tiny pocket model at $24 to a four-wave super with big loudspeaker. Tape recorder prices are generally stable.

Prominent among the 210 foreign exhibitors of electrical and electronic equipment at Hanover were Texas Instruments Incorporated and Minneapolis-Honeywell. Texas Instruments was represented by subsidiaries Texas Instruments Limited of Bedford, Eng., and Metatappa N.V. of Almebo, Holland.

A check made by ELECTRONICS shows the following trends:

(1) Altogether some 21 million tv sets will be produced in Germany through 1960 as against 1.85 million in 1959. Color tv is in an advanced stage of development but will be commercially unfeasible until prices can be lowered.

(2) Radio sales in 1959 reached the record 41 million mark. Manufacturers see a flattening out of the curve through 1960 with major sales emphasis on fully-transistorized portables. All-transistor auto radios should revitalize this section of the industry.

(3) The recent slashes in sales prices should boost production of stereophonic high-fidelity units to the detriment of monaural phonographs.

(4) Binaural tape for stereo equipment is on the market but manufacturers believe that it is too early and too expensive to create customer interest.
“In half an hour, she’ll dock right at our new plant”

Your deepwater plant site and your favorite water sport can be only minutes apart in Virginia’s Hampton Roads area. From beach or boat basin or even your front porch, you can see the parade of modern freighters that links this busy port directly to some 300 world markets... with a sailing on the average of every hour the year around. □ Ask VEPCO about the excellent rail, highway and airline service... the mild climate... the friendly communities and thrifty government that have combined to bring many nationally known industries to this key area. And without cost or obligation, let VEPCO be your confidential scout for a deep water plant site here. Write, wire or phone soon.

TWO NEW CBS FRAME-GRID WIDEBAND PENTODES

Exclusive new CBS E280F/7722 and 7721 sharp-cutoff, 9-pin miniature pentodes offer you the highest ratings ever for gain-bandwidth product. The premium quality tubes make possible new high levels of performance in i-f and video stages of industrial and instrumentation equipment. You benefit from fewer stages, fewer tubes, fewer passive components, and fewer interconnections... due to the many advantages of true frame-grid construction.

Order from your local sales office or Manufacturers Warehousing Distributor. Get technical bulletins T-1006 and T-1007. Ask about other CBS frame-grid types. Watch for many new announcements on the rapidly expanding CBS industrial tube line.

Industrial Controls in Britain

Here's a survey of U.K.'s progress.

National Automation Center may be set up

LONDON—British progress in the industrial controls field over the last five years has been slow, but there are some bright spots. Of special importance now is the fact that the suggestion is being widely circulated in industry that the government, through its Dept. of Scientific and Industrial Research, set up a National Automation Center.

At the center a staff of specialists would deal with industrial queries while a permanent exhibition of typical applications would point up economic advantages and sell executives on control systems.

'Strong In Ideas'

Another sign of British activity in the industrial controls field was the recent move by Production Engineering Ltd., a large consulting firm, to set up a special section for automatic inspection systems. David Nicolson, firm's managing director, told McGraw-Hill World News:

"We want to generate in the industry the same enthusiasm for automatic inspection as British industry now has for the currently fashionable diversification rage. Money spent on modernizing the existing methods can often eliminate the need to diversify."

Automation consultant David Foster surveyed 100 British companies, concluded: "Britain is strong in ideas but user industry lags in their adoption. It is two to five years behind the States."

Here are his ratings of British firms in 10 fields of control:

- Batch process sequencing and dispensing control—Good progress.
- This sector is forging ahead, especially in automatic dispensing of solids and liquid mixes from punched card and tape recipes. Wide acceptance is largely due to adoption of simple telephone techniques involving stepping switches in standard functional units. Solid-state actuator monitoring systems are being introduced.
- Computer controlled processes—Still exploratory.
- With most chemical and oil companies still engaged in exploratory simulator studies, Britain is probably a couple of years behind the U.S. in this work. A recent symposium showed steady work on the theoretical foundations but no applications.

Machine tool control—Little commercial penetration.

Apart from point-to-point positioning in the jig-boring and spot welding fields, most projects are still restricted to aircraft special parts manufacture. To date there is no great penetration into commercial applications, these being still firmly wedged to older copying techniques. Development engineers are searching for cheap systems at $6,000 per dimension with an 0.0002 in. accuracy.

Automated shipbuilding—A good starter.

Computer calculation of ship plate profiles coupled to automatic flame cutting systems are planned to eliminate the moulding loft. This is one of Britain's great hopes as a shipbuilding nation.

Automatic inspection machines—Lagging.

In production line automatic inspection machines, Britain lags be-
cause even her longest production run does not yet approach the four-
million-piece-part annual output re-
quired for an economic break-even
point on these techniques. The Brit-
ish market is for a machine that is
adaptable for batch production runs
of the odd 1,000 or so. How to
achieve this economically is the de-
signers’ current problem. One ap-
proach, which if successful would
leapfrog Britain ahead of the inter-
national position, is using optical
techniques for dimensional inspec-
tion without jiggling the product.

Automatic assembly systems—
Little movement.

Low labor rates for semi-skilled
workers still fail to make automatic
assembly systems an attractive eco-
nomic proposition in the U.K.
There is little activity in the field
and what there is in the radio set
production follows U. S. practice.

Automatic identification systems—
Bubbling.

Just about to break in Britain is
the identification of shapes and
code marks on mixed products flow-
ing down conveyor lines. In other
fields a coded photoelectric recog-
nition system on London buses is
giving centralized information on
bus positions along their routes.
Experimental installations are un-
der consideration for railroad mar-
shalling yards.

Automated stores—A dark horse.

Although way behind the U. S.,
the current high user interest and
the set-up of a new British combine
with a license from an American
firm is expected to move this cate-
gory way up the list of practical
automation hardware in the next
few years.

Road traffic control—A new
entry.

The threatened strangulation of
the country’s road system will call
for more highly automated traffic
signal control. A concentrated at-
tack here might give Britain a lead
in this field.

Monitoring production flow items—
Good start.

Steel industries in particular
have applied automatic monitoring
systems to keep tabs on billets flow-
ing through the mills. With such
systems basically pioneered by the
government-sponsored Department
of Scientific and Industrial Re-
search, this is likely to spread fast
to other industries.

More Standard Ratings
For Styraco®
Film Capacitors

The Sprague Electric Company has
increased the number of standard
catalog ratings of its Styraco poly-
stryene capacitors in both submini-
ature metal-clad tubular and drawn
bathtub cases. In addition, large
threaded-neck cases have been added
to the tubular designs in order to
meet more severe military vibration
requirements.

These capacitors will be of special
interest to electrical circuit designers
working in the field of digital com-
puters, precision timing circuits,
high-Q tuned audio circuits, low-
frequency filters, bridge measurements,
and similar applications.

The special electrical qualities of
polystryene film permit the design of
capacitors with virtual freedom from
dielectric absorption, extremely high
leakage resistance, extremely low
power factor, and excellent capaci-
tance stability and retrace. The tem-
perature coefficient of capacitance,
approximately -120 ppm/°C, is
practically linear over the full oper-
ing range of -55 C to 85 C, and is
almost entirely independent of
frequency.

For complete technical data on
Styraco Film Capacitors, write for
Bulletin 2510A to Technical Litera-
ture Section, Sprague Electric Com-
pany, 35 Marshall St., North Adams,
Massachusetts.

The DIDAS transmitter

DIDAS receiving and recording in laboratory conditions

Speedy measurement and analysis of data has become a necessity in modern industry. Armstrong Whitworth Aircraft have developed data handling systems for measurement and remote control. The data can be transmitted at the speed of light by radio, or by cable link, with extreme accuracy.

In one system (the DIDAS vehicle system), over 250,000 different readings can be obtained in one minute. Analogue/digital and digital analogue converters, working at over 50,000 conversions a second, eliminate processing bottlenecks. Systems can be engineered to customers' requirements.

ARMSTRONG WHITWORTH AIRCRAFT LIMITED, Baginton, Coventry, England
(A member of Hawker Siddeley Aviation)
GOOD-ALL 601PE CAPACITORS

"fit" like a disc PLUS...

...Temperature STABILITY

Identical to high quality tubular capacitors and far superior to that attainable with high capacity discs.

MILITARY APPLICATIONS—Widely used in military equipment; also well suited to high quality civilian instrumentation where space is critical.

Tailored for TRANSISTORS

Wafer-thin shape permits great flexibility in tight chassis layouts. The 601PE is competitive in price with ceramic discs in the range of .1 MFD and above.

SPECIFICATIONS

Insulation Resistance—Greater than 75,000 megohms when measured at 100 volts D.C. at 25°C, for a maximum of 2 minutes.

Capacity Tolerance—Standard tolerance is 20%.

Winding Construction—Extended foil (non-inductive) MYLAR Dielectric.

Lead Variations—Formed or straight leads.

Dissipation Factor—Less than 1% at 1,000 cycles per second at 25°C.

Dielectric Strength—100 volts D.C. for 1 to 5 seconds through a minimum current limiting resistance of 100 ohms per volt.

Temperature Range—May be operated at full rated voltage to 85°C. Derate to 50% when operating at 125°C.

See AUTHORIZED DISTRIBUTOR list on facing page.

NEED PRODUCT INFO? LOOK IN THE NEW electronics BUYERS' GUIDE

You'll find detailed facts about the products of almost 700 different advertisers — that's 42% more than you'll find in any other electronics directory.

There's also 64 pages of reference data about markets, materials and design — vital information for all working in electronics. Also local sales offices of manufacturers . . . the names, addresses and phone numbers of representatives . . . complete lists of manufacturers . . . registered trade names . . . and also, of course, the most complete listing of all electronic and related products. Tells what you want to know . . . when you're ready to buy.
Russia Plans New Satellites

"Whole series" will be part of a vast undertaking, reports Soviet academician

MOSCOW—Soviet Union is planning "a whole new series of new artificial satellites," Academician Anatoly Blagonravov is quoted in Soviet Weekly.

Blagonravov said the vast undertaking "will cover study of ultraviolet radiation and X-rays in the spectra of the sun and other celestial bodies, mapping the starry sky in various spectral lines, photographing solar corona and nebulae."

He said the program also "provides for further investigations of cosmic rays, the structure of the earth's magnetic field and its relation to solar activity, the degrees of ionization and composition of the ionosphere, as well as its condition for radio wave propagation."

High-Precision Measuring

The academician said there are plans to study the earth's gravitational field and to take high-precision time measurements for astronomical purposes.

"The second major line of research," he reported, "will be continued investigation of the moon and the area around it. At a later stage, relying on the experience we have gained, we hope to carry through a whole series of experiments with rockets to be sent to planets of the solar system, and above all, Mars and Venus."

Blagonravov disclosed "extensive biological investigations are planned in preparation for human travel in space." He said the experiments would involve a comprehensive study of the effects of cosmic radiation on living organisms and methods of protection.

The Soviet scientist said special containers with plants and animals would be sent into space near the earth. He noted that the delivery of scientific instruments to the surfaces of other planets would permit scientists to determine their habitability.

Blagonravov said space problems could be conquered best if scientists of all nations work together.

Sun Powers Japanese Lighthouse Beacon

Solar battery containing 648 silicon cells powers the warning light atop Japanese lighthouse (left) which has operated successfully since November.

Japan's Maritime Safety Agency said recently it would build six more solar installations to reduce ship accidents along the Seto Inland Sea coast.

Sunlight converter, which is made by Nippon Electric Co., charges a 12-volt nickel-cadmium battery during the day.

At night the power lights a 10-watt bulb for two flashes of 1½ seconds in a 7-second cycle. Flash reaches 9 miles. Photo at right shows a closeup of the warning beacon behind solar battery.
FOR SUPER-FINE CUTTING
OF HARD, BRITTLE
MATERIALS...

THE
Industrial Airbrasive Unit

We don't recommend slicing up the family's fine Limoge China, but this does illustrate the precisely controlled cutting action of the S. S. White Airbrasive Unit. Note how clean the edge is, and how the delicate ceramic decoration is unharmed.

The secret of the Airbrasive is an accurate stream of non-toxic abrasive, gas-propelled through a small, easy-to-use nozzle. The result is a completely cool and toothless cutting or abrading of even the most fragile hard materials.

Airbrasive has amazing flexibility of operation in the lab or on an automated production line. Use the same tool to frost a large area or to make a cut as fine as .008"!...printed circuits...shaping and drilling of germanium and other crystals...deburring fine needles...cleaning off oxide coatings...wire- stripping potentiometers...engraving glass, minerals, ceramics. Jobs that were previously thought impossible are now being done.

Send us samples and specs on your difficult jobs and let us test them for you.

NEW BORG MICRODIALS ADD RICHNESS AND STYLE TO CONTROL PANELS AND INSTRUMENTS

Now from Borg, originator of famous Microdials, comes a fresh, new concept in turn-counting dial appearance... Series 1360 Microdials. These new Borg Microdials were specially developed to add style and color to electronic control panels and equipment. Available in five smart models of red, gray and black color variations. Colors are inlays of colored plastic... will never wear, scale or rub off. Quality mechanical features such as smoothness of action... absence of noise... fewer ambiguities in reading and setting assure accurate, reliable performance. Contoured brake arms lock settings in place, but do not interfere with reading and setting. Catalog data sheet BED-A137 gives complete color combinations and specifications. See your Borg technical representative or distributor, or let us put him in touch with you.

NEW!  MILLIMICROSECOND PULSE GENERATOR

Model 120B  f.o.b. Oakland, Calif.  $1275

- RISE TIME OF LESS THAN 2.5 MILLIMICROSECONDS
- REPETITION RATE OF 10 cps to 10 Mc

plus these other features
- PRECISION PULSE WIDTHS 2.5 to 25 millimicroseconds
- INDEPENDENT OUTPUTS Two fully controlled 0-8 volt outputs
- FLEXIBLE Internal or external drive, provision for external gating and single pulse operation

Here is a new all-electronic instrument with the performance features—and quality engineering—you need for advanced applications. The 120B’s fast rise time and high repetition rate make it unexcelled for general laboratory use in development, production and testing of diodes, fast transistors, cables, pulse transformers, delay lines and video amplifiers...for development and check-out work in the computer field, for rf applications, and in nuclear test work. For more information on the 120B or other E-H pulse generators, write or wire E-H.

SPECIFICATIONS
RISE TIME (10% to 90%)
Less than 2.5 millimicroseconds
PULSE WIDTH
2.5 to 25 millimicroseconds
REPETITION RATE (External or Internal)
10 cps to 10 Mc
OUTPUTS
(Two Independent Output Channels)
Amplitude, 0 to minus 8 volts (use E-H model 41 pulse transformer for polarity inversion and impedance matching)
Impedance, 93 ohms
TRIGGER OUTPUT
Positive 15 volt pulse
CONNECTORS
All BNC type
TRIGGER ADVANCE
120 millimicroseconds
EXTERNAL DRIVE
Delay, 50 millimicroseconds
Amplitude required, 3 volts rms
ELECTRONIC GATE
Gating time, less than 100 millimicroseconds
Amplitude required, positive 20 volts

EXPANDING THE
OF SPACE TECHNOLOGY IN

COMMUNICATIONS

Lockheed's interest in developing the science of communications extends from the depths of the oceans to deep space. Its Missiles and Space Division research programs deal with the development and application of statistical communication and decision theory in such areas as countermeasures; telemetry multiplexing and modulation; scatter communications; multiple vehicle tracking; millimeter wave generation and utilization; sonic signal detection and processing; avoidance of multipath degradation; and interference avoidance.

Associated research and development efforts are directed toward propagation studies and advanced antenna design; low noise amplifiers; vehicle borne signal transmission and reception, data storage and processing; solid state materials and devices.

The scope of such activities extends from advanced studies of naval communication problems on and under the oceans; the many applications to satellite vehicles; on to the specialized communication problems of deep space explorations. Latter needs are exemplified by high frequencies, low weight and power, high stability, low effective bandwidth, extreme reliability and basic simplicity requirements.

Engineers and Scientists: Investigating the entire spectrum of communications is typical of Lockheed Missiles and Space Division's broad diversification. The Division possesses complete capability in more than 40 areas of science and technology — from concept to operation. Its programs provide a fascinating challenge to creative engineers and scientists. They include: celestial mechanics; communications; computer research and development; electromagnetic wave propagation and radiation; electronics; the flight sciences; human engineering; magnetohydrodynamics; man in space; materials and processes; applied mathematics; oceanography; operations research and analysis; ionic, nuclear and plasma propulsion and exotic fuels; sonics; space medicine; space navigation; and space physics.

If you are experienced in work related to any of the above areas, you are invited to inquire into the interesting programs being conducted and planned at Lockheed. Write: Research and Development Staff, Dept. E-22, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship or existing Department of Defense clearance required.

Here are the plain facts!

... why it pays to specify and use dependable BUSS FUSES

IT'S A FACT! By specifying BUSS fuses, you obtain the finest electrical protection possible — and you help safeguard the reputation of your product for quality and reliability.

IT'S A FACT! BUSS fuses have provided dependable electrical protection under all service conditions for over 45 years — in the home, in industry and on the farm.

IT'S A FACT! To make sure BUSS fuses will give your equipment maximum protection, every one made is tested in a sensitive electronic device. Any fuse not correctly calibrated, properly constructed and right in all physical dimensions is automatically rejected.

IT'S A FACT! Whatever your fuse requirements, there's a dependable BUSS or FUSETRON fuse to satisfy them. Sizes from 1.500 ampere up and there's a companion line of fuse clips, blocks and fuseholders.

IT'S A FACT! The BUSS fuse engineering staff will work with you to help you find or develop the best-suited to your needs. This places the world's largest fuse research laboratory and its personnel at your command to save you engineering time.

For more information on BUSS and FUSETRON Small Dimension fuses and fuseholders, write today for Bulletin SFB.

BUSS fuses are made to protect — not to blow, needlessly.
BUSS makes a complete line of fuses for home, farm, commercial, electronic, electrical, automotive and industrial use.
Higher permeability values now guaranteed for Allegheny Ludlum’s Moly Permalloy

Means new, consistent and predictable magnetic core performance

Molybdenum Permalloy nickel-iron strip is now available from Allegheny Ludlum, with higher guaranteed permeability values than former typical values. For the buyer, this new high quality means greater uniformity . . . more consistent and predictable magnetic core performance.

This higher permeability is the result of Allegheny Ludlum’s intensive research on nickel-bearing electrical alloys. A similar improvement has been made in AL-4750 strip steel. A-L continues its research on silicon steels, including Silectron, well-known grain-oriented silicon steel, and other magnetic alloys.

Complete facilities for the fabrication and heat treatment of laminations are available from Allegheny Ludlum. In addition, you can be assured of close gage tolerance, uniformity of gage throughout the coil, and minimum spread of gage across the coil-width.

If you have a problem relating to electrical steels, laminations or magnetic materials, call A-L. Prompt technical assistance will be yours. And write for more information on Moly Permalloy. Allegheny Ludlum Steel Corporation, Oliver Building, Pittsburgh 22, Pa.

Address Dept. E-5.

New Sub-Subminiature "1SX" Switch with Gold Contacts

The new "1SX" switch is the smallest single-pole double-throw, snap-action switch available with enclosed gold contacts. It weighs only 1/28 of an ounce and is so small it can hide behind a dime. Designed for use on dry circuits, the "1SX" can be specified for computers, missile applications and other installations involving low energy circuits. A number of different actuators are available. Turret-type terminals are used to permit easy wiring and strong wrap-around lead wire connections. The gold contacts operate with the exclusive MICRO SWITCH snap-action spring, fabricated from beryllium copper. Write for Data Sheet No. 175 on the new sub-subminiature "1SX," with MICRO SWITCH precision and the absolute maximum in reliability.
maximum in reliability!

MICRO SWITCH offers three important series of ultra-small basic switches with corrosion-proof gold contacts which provide long shelf life in applications involving low electrical loads. They are available with many different integral and auxiliary actuators.

Subminiature "SM" Series—These gold contact models have single-pole double-throw contact arrangement. A choice of terminals includes: "T" type turret design, solder terminals, double-turret terminals, and "quick-connect" terminals for fast, solderless wiring.

"V3" Basic Switches — Postage stamp size gold contact designs, can be used singly or gang-mounted in assemblies. "V3" Basics are available with many different types of auxiliary actuators.

For engineering help on highly reliable gold contact basic switches for low energy circuits, see the Yellow Pages for the name of the nearby MICRO SWITCH branch office. Ask for Data Sheet 175. MICRO SWITCH has wide experience in electronic applications requiring the advantages of switches with gold contacts.
On their Rotary Component testing and handling techniques

We have been supplying rotary components to U. S. Gauge for 11 years. Of 14,744 units shipped to U. S. Gauge over the past 20 months, only 308 have been rejected by them. After return to our plant of these 308 units, and subsequent re-examination and retest by the CPPC Quality Control Department, CPPC agreed that 164 of these 308 units did not meet acceptable quality standards when retested. 164 of 14,744 units shipped is a quality rejection rate of only .0111!

Included in the 164 rejections were ultra high temperature units capable of withstanding 450° F which call for higher than ordinary quality standards of manufacture.

This is not only proof of CPPC quality, but is possible only if the customer is equally scrupulous and careful in his utilization; and it demonstrates U. S. Gauge's excellent handling of quality products in their plant.

During this 20 month period, Clifton Precision was under the heaviest pressure for deliveries in its history, but was still able to deliver 14,580 acceptable units 9 calendar days ahead of promised delivery schedules on an average.

Rapid increases in complexity of
electronic equipment have created
a serious need for reliable micro-
miniature packaged circuits. In
fact, on many proposed electronic
systems the random failure rates
for present-day components may
cause the average time between
failures to be so short that accept-
able performance will be unobtain-
able. Some believe that a major im-
provement in reliability should be
the prime objective of microelec-
tronics work; others think that a
significant reduction in size and
weight is paramount; and still
others feel that a cost reduction
should be the main objective. This
article reviews the concept of Solid
Circuit semiconductor networks and
discusses why they can provide bet-
ter reliability, smaller size and
weight, and ultimate savings in
total equipment cost when compared
with subminiature components or
with other approaches.

There are many different types of
microminiature packaged cir-
cuits or functional devices such as
ceramic-base printed circuits, mi-
crocircuits, micrologic elements, mi-
cromodules, molecular electronics,
semiconductor networks and thin
films. A description and comparison
of all these types is outside the
scope of this article; however, it
may be helpful to consider one
method of categorizing this work.

The first major category includes
the redesign of conventional com-
ponents to change their form factor
and the development of assembly or
packaging techniques for these new
components. This category may be
subdivided into assemblies that re-
quire a stack of substrates, each of
which contains only a few compo-
nents, and assemblies that have all
the required circuit elements fabri-
cated on one substrate. In either
assembly, there is a one-to-one cor-
respondence between each component in the microminiature package and the same component in an operating breadboard of the circuit. Thus there are the same number of lead wires, conducting paths and interconnections. Unfortunately, there is no way to fabricate a transistor as an integral part of the package. Each active element must be separately fabricated, inserted or mounted in the package, and then electrically connected to the other components. Some miniaturization approaches in this category are using uncased or bare transistor wafers.

The production and shipment of reliable transistors without a hermetically sealed package presents several new problems. Adequate surface passivation is one of these problems. Although the can and header are quite large compared with the size of the active element, to eliminate completely these items and work with unprotected wafers may deteriorate transistor performance and reliability because of unknown surface contamination.

The second major category of microelectronics work includes those devices that have a complete circuit fabricated on or within one or more blocks of semiconductor material. Solid Circuit semiconductor networks are in this category. By combining oxide masking, diffusion, metal deposition, alloying, and surface shaping, complex networks are fabricated using single-crystal semiconductor wafers for both active and passive components. Individual circuit elements are difficult to distinguish because there are few internal junction points. The resultant devices frequently have performance characteristics that can be best explained by using distributed-constant networks. We have a three-dimensional circuit; however, there are no discrete components soldered from one point to another. Thus a direct comparison between a semiconductor network and a conventional circuit is best made on a functional basis. The problem of individually protecting and packaging components has been eliminated. Also, by using one homogeneous high-purity material for all circuit elements, the number of contacts between dissimilar materials is reduced so that the majority of electrical connections or junction points are for input, output and power supply leads.

Recent talks and technical articles have generated some confusion regarding the state of the art. Part of this confusion is the result of combining discussions on micro-miniaturization with the concept of a semiconductor functional device. Before the latter can be of value in complete microelectronic systems, there must be an orderly approach to the design of each new function. Also, a useful semiconductor functional device must be reproducible. Most of the functional devices proposed in the past four years have contributed little to the advancement of microelectronics because they pose insuperable problems.

Solid Circuit semiconductor networks were first announced in March 1959. Today, they are in pilot production. This progress was possible because semiconductor networks are fabricated with much of the same technology and equipment that have been perfected in the production of mesa-type transistors.

Typically, only 15 or 20 process steps are needed to convert a semiconductor wafer into a network. With so few process steps, it becomes economical to apply a high degree of process control. This is one more reason why reliability is built-in. The fabrication details to be discussed are intended to show how conventional transistor processing steps are related to those required to produce semiconductor networks.

Although semiconductor devices may be analyzed from basic principles governing current flow in solids, their three-dimensional nature complicates the problem. The fact that accurate mathematical treatments are not available
for many common transistor structures is an indication of the complexity of three-dimensional device mathematics. Consequently, there are no simple theoretical procedures that can be used to translate a desired circuit into a functional device.

Thus, semiconductor networks are designed by relating sections within a semiconductor to conventional circuit elements. Certain regions are considered as resistors, others as capacitors, diodes, transistors or as any other device that can be formed from a semiconductor. Any number of such regions may be arranged to form a desired circuit. Since these regions may lie entirely within a single semiconductor wafer, the resulting structure is fully integrated.

It often is impossible to identify the individual regions in a functional device; however an existing circuit may be translated into an equivalent semiconductor network by relating known circuit elements to conductance paths in the semiconductor. If electrical properties of the various regions are known, performance of the finished device can be calculated. As an alternative, the regions may be simulated with conventional components and the circuit breadboarded for evaluation.

The region between any pair of ohmic contacts on a homogeneous semiconductor will act like a resistor, where the equivalent value of resistance is a function of material resistivity, length and cross-sectional area of the region. Such resistors are linear and closely follow Ohm's law for the voltages encountered in transistor circuits. Since current conduction takes place within the bulk of the material, these resistors are not subject to many of the changes with time and load that occur in deposited thin films. With the proper selection of material, the resistance temperature coefficient may be accurately controlled. For example, if high-resistivity silicon is used, the resistance may increase as much as 7,000 parts per million per deg C, or it may decrease for heavily doped low-resistivity material.

Resistance regions may be formed from a uniformly doped wafer as shown in Fig. 1A, or diffusion techniques may be used to produce a thin surface layer of opposite conductivity type, shown in Fig. 1B and 1C. In the latter, the resultant p-n junction is a barrier that confines current flow to a region near the surface. Since diffused-layer resistors have a resistivity that varies as a function of distance from the surface, their equivalent value of resistance is not as easy to calculate as for the bulk resistor. High-resistivity material is usually used for bulk resistors, while diffused-layer resistors may use low-resistivity material. Resistors produced by either process are formed from single-crystal material. This means they have extremely good noise properties because current conduction is entirely within one crystal; conduction does not take place between individual particles of resistance material. There is no absolute limit on the resistance value which may be produced by diffusion techniques; however, size restrictions and typical material resistivities make it desirable to limit maximum values to about 40,000 ohms for bulk resistors.

A reverse-biased p-n junction may be used as a capacitor (Fig. 1D), where the depletion region at the junction serves as the dielectric. For a given material, the capacitance is a function of the width of the depletion region and the junction area. For silicon, capacitance values up to 200,000 pf per sq cm are possible. Breakdown voltages of several hundred volts can be obtained with a low temperature coefficient of capacitance. Since the width of the depletion region changes with applied voltage, a non-linear response results. Although this effect has been used to advantage in many applications, capacitors of this type are not suitable for high-level linear circuits. Another disadvantage is that the capacitors are polarized, and must be connected so that the junction is not forward-biased.

For applications where linearity is important, or where reverse bias cannot always be maintained, another type of capacitor can be formed on silicon wafers. The dielectric in these capacitors consists of a silicon-oxide layer formed on the surface of the silicon, as shown in Fig. 1E. The semiconductor serves as one plate of the capacitor and a layer of metal is deposited on the oxide for the second plate. Since the oxide is formed on a single-crystal wafer the oxide is unusually free of defects. Oxide-type capacitors have temperature coefficients well below 100 parts per million per deg C, low voltage coefficients and excellent stability with time. For 50-volt breakdown ratings, capacitances of 50,000 pf per sq cm can be obtained.

Although large values of junction or oxide-type capacitors may be fabricated, for extreme miniaturization it is necessary to limit the maximum capacitance. The limit

**FIG. 3—Fabrication flow chart for semiconductor networks**
for junction-type capacitors is between 2,000 and 5,000 pf depending on the number of other components required. A similar limit for oxide capacitors would be from 500 to 1,000 pf.

Distributed-constant resistor-capacitor networks are readily formed in semiconductor networks. One type of distributed R-C network is shown in Fig. 2A. Several ways to connect its three terminals are shown in Fig. 2B. Such networks have many useful properties, particularly for low-pass filters or phase-shift networks. A distributed R-C network used as a low-pass filter will have much sharper cutoff characteristics than a three-stage lumped-constant network and will provide more attenuation for a given R-C product. Phase-shift networks constructed in this manner have more phase shift for a given attenuation than a lumped-constant equivalent. Because of the layerized nature of the structures, distributed-constant networks are particularly easy to fabricate and thus are frequently used.

The remaining passive circuit element to be discussed is the inductor. Inductance is a measure of flux-linkages per unit current. Since a finite volume is required to link lines of flux, it is difficult to imagine a one-henry inductor comparable in size to a match head. At present, there is no microminiature semiconductor device that will produce the equivalent characteristics of a very large inductor. A recent conference paper described a semiconductor diode with an equivalent circuit that had, under certain conditions, a high-Q large inductance in series with a negative resistance. Also, it is possible to realize an inductive reactance between two terminals by using active network techniques.

One possible solution is to simulate the required function. For example, semiconductor delay lines may be used to replace an inductor in a time-delay circuit; R-C networks may be used in place of L-C tuned circuits; field-effect devices may replace chokes; or impedance matching by circuit design may replace transformers. Also, a small spiral of semiconductor material may be built to actually realize an inductor. However, when henries of inductance are necessary or if the skirt selectivity of an L-C network cannot be sacrificed, the best solution is to build a hybrid unit which combines a semiconductor network with a separate inductor. So far, this problem has not been serious because we have concentrated our design efforts on computer and switching-type circuits.

Diodes and transistors may be fabricated by either diffusion or alloying. The diffusion process is extremely flexible; it is currently used for some of the highest power and highest frequency devices. For this reason, and because of the excellent reproducibility of diffused devices, most semiconductor networks which have been produced use diffused structures. Diodes produced have been similar to the 1N645 and 1N659 series, while most of the transistors produced have been electrically similar to the 2N702 and 2N706.

Many other types of devices may be formed in a semiconductor network. Unipolar or field-effect transistors, tunnel diodes, pnpn devices, varactors, solar cells and thermoelectric elements are all possible.

The processes used in fabricating any semiconductor device are largely determined by yield considerations consistent with the desired operating characteristics of the finished unit. These characteristics include not only the electrical parameters, but such items as reliability and temperature stabilization. In fabricating Solid Circuit networks there are two additional considerations: design versatility and functional optimization. Since each semiconductor network is a complete circuit rather than a single component, an almost infinite variety of designs is possible. To satisfy any percentage of the possible applications, a large number of different types needs to be fabricated.

Semiconductor network processes must therefore lend themselves to design change without costly and time consuming mechanical tooling. On the other hand, the processes must allow the circuit to be functionally optimized. Complete optimization of a transistor is always opposed by design compromises. For example, the transistor designer must compromise between low base resistance and high current gain. The circuit designer, however, may use transistors with both low base resistance and high current gain in the same circuit to achieve better performance. For the same degree
Optimization in a semiconductor network, both transistor characteristics must be fabricated on the same semiconductor wafer. This introduces an additional degree of process control that is not necessary in conventional transistor production.

To unconditionally meet the foregoing considerations and make practical the production of semiconductor networks, unique combinations of techniques which include photographic resist, oxide masking and gaseous diffusion have been used. Although many of these techniques have been used in mesa transistor fabrication, their full technological capability becomes apparent in semiconductor networks.

The sequence of operations, outlined in Fig. 3, will be recognized by semiconductor device engineers as being applicable to many types of devices. Since the basic techniques are well known, they will be only briefly reviewed here; the major emphasis will be placed on their adaptation to semiconductor networks. It is significant to note the steps in which the units are simultaneously processed versus those in which they are individually processed. For uniformity, reliability, and good yield, as many of the steps as possible should involve simultaneous processing, that is, fabrication of large numbers of units at the same time under the same conditions and on the same wafer.

The semiconductor material is grown as a single crystal and then sliced, lapped, and polished in exactly the same way as other devices. This processing step can be eliminated if dendritic crystals become economical to produce. Whereas both silicon and germanium have been used for semiconductor networks, silicon appears to be superior because of higher intrinsic resistance, ease of forming selective masking against diffusion, and better results in surface stabilization. Diffusion masks have been formed on germanium by using evaporated coatings, but this adds complexity to the operation. The remainder of this article will therefore be limited to the use of silicon material.

For a given geometry, resistivity of the starting material affects the value of any bulk resistors in the finished device; therefore, material resistivity must be accurately controlled. A resistivity measuring bridge is used to sort silicon wafers before fabrication is started. Material resistivities around 10 ohm-cm are satisfactory for the resistance values found in most computer-type applications. Also, resistivities in this range have been quite insensitive to subsequent processing.

Controlled amounts of impurities must be introduced into a bulk semiconductor to form p-n junctions. Two common techniques for adding these impurities are alloying and diffusion. In alloying, an impurity metal such as aluminum is first deposited on the semiconductor surface. The wafer is then heated to melt the metal and dissolve some of the semiconductor. Upon cooling, the molten region solidifies in single-crystal form with the same orientation as the original semiconductor. Included in the crystalline lattice of the regrown region are impurities of the deposited metal which give the regrown region the desired conductivity type. For p-n junction formation this would be a type opposite to the bulk type. Because alloying is a melting and freezing process, it occurs rapidly and is somewhat difficult to control in depth. The amount of impurity included in the regrown layer is a function of the thermodynamic properties of the metal-semiconductor system (phase diagram) plus the thermodynamics of the heat cycle (departures from equilibrium). In practice, these considerations limit the impurity concentrations to a narrow range of values.

Diffusion, as contrasted with alloying, is a relatively slow method of introducing impurities into a semiconductor so that better depth and concentration control are obtained. The diffusion process consists of heating the silicon to approximately 1,200 °C in the presence of an impurity gas. The gaseous impurities strike the surface and diffuse into the wafer to form an n- or p-type layer, depending on the characteristics of the impurity. In diffusion n-type junctions into p-type parent silicon the diffusant may be: antimony, arsenic, bismuth or phosphorus. In diffusing p-type junctions into n-type parent silicon the diffusant may be: alumi-
num, boron, gallium, indium or thallium. Selection of a particular diffusant depends on what penetration and surface concentration of impurity atoms is desired. Different impurities diffuse at different rates; thus two impurities may be diffused simultaneously to form two p-n junctions at the same time. Diffused junction depths in silicon may be accurately controlled from hundredths of a mil to several mils.

To control the surface concentration it is necessary to control the number of impurity atoms which reach the silicon surface during the diffusion cycle. This can be done by vacuum sealing the diffusant together with the wafers in a tube (closed-tube method); or by controlling the temperature, and hence the vapor pressure, of the diffusant independent of the silicon temperature (open-tube method); or by applying the diffusant directly to the wafers before heating (paint-on method). Each diffusion technique has certain advantages. The method used depends on the device to be fabricated and the accuracy that is needed to secure good control on the device parameters.

A closed-tube diffusion furnace is sketched in Fig. 4A. The silicon wafers are placed in the quartz capsule, the spacer is inserted, and then the small quartz boat containing the diffusant is inserted. The quartz tube is then evacuated, sealed and placed in a furnace so that the wafers and diffusant are at the same temperature. This process has been used in transistor production for several years.

A sketch of open-tube diffusion equipment is shown in Fig. 4B. Open-tube diffusion requires two furnaces in tandem. The smaller furnace is the source furnace and the larger furnace is the diffusion furnace. A carrier gas—argon, hydrogen, nitrogen or oxygen—flows at a controlled rate into the quartz furnace tube at the source-furnace inlet side. The diffusant is heated in the source furnace and evaporates at a controlled rate. The carrier gas picks up the diffusant as it passes over the heated source boat and carries the diffusant to the heated semiconductor wafers where it is deposited. The wafers are at a higher temperature than the evaporating diffusant. Temperature is controlled in both the source and diffusion furnaces with the same accuracy as in the closed-tube furnace.

The paint-on method utilizes a diffusant-enriched solution which is painted on the semiconductor wafers. In some cases the wafers may be dipped into the solution. The wafer is then placed in a furnace and diffusion occurs at an elevated temperature.

The junction area of alloyed devices can be controlled by limiting the regions where the impurity metal is deposited. In diffused structures the junction areas may be controlled by forming an oxide mask on the silicon. If silicon is heated in an oxidizing atmosphere, the resultant layer of oxide will mask against diffusion impurities such as boron and phosphorus. By selective removal of this silicon-oxide layer, which forms uniformly over the surface, area control of the diffused layers can be achieved.

The selective removal of an oxide mask is accomplished by photoetching techniques similar to those used in making etched-circuit boards. This process is illustrated in Fig. 5 for the special case of an n-type diffusion into a p-type silicon wafer. The photographic resist is applied in liquid form, usually by dipping the material in resist. After drying, the resist forms a thin plastic film which is photographically sensitive to ultraviolet light. Exposure is accomplished by contact printing through a photographic negative that has been produced by laying out the desired pattern at 50 to 100 times actual size and then photographically reducing it. Thus the only tooling required to produce a different oxide mask is to change the photographic negative. Typical reduced negatives have opaque areas with dimensions on the order of one mil.

The photographic exposure jig permits alignment of the negative with respect to patterns already on the wafer. Exposure of the photoresist causes it to be insoluble in the developer. Therefore, resist under the opaque areas of the negative will be removed by the developer while resist under the clear areas will remain. If the wafer is now placed in a hydrofluoric acid bath, the oxide will be removed where it is unprotected by the resist. Hydrofluoric acid attacks only silicon oxide and not the underlying silicon or the photoresist.

In addition to controlling the junction geometry, oxide masking also may be used to control the impurity concentrations. By oxide masking certain areas during only part of the diffusion cycle, while exposing other areas during the entire cycle, surface layers of different concentrations and depths may be obtained. For example, a series of diodes having different breakdown voltages can be formed on the same wafer.

The active areas are completed once the junctions have been

---

**FIG. 6**—Example of selective etching using photoresist

formed. In the finished device, electrical connections must be made to these various p- or n-type layers and to the bulk material. Often the current path is through the semiconductor itself, but ultimately some outside connection is required. Two steps are involved in making these connections: first, a nonrectifying low-resistance metallic contact is made to the semiconductor; second, leads are attached to these contacts. The contacts are made by depositing metal on the semiconductor surface and then forming an alloy by heat treatment. This is the same process previously discussed for making alloyed p-n junctions, only in this case the impurity metal involved is of the same conductivity type as the semiconductor. Thus p-p' or n-n' junctions are formed (the + notation indicates a much higher impurity concentration).

This process, like the others involved in semiconductor network fabrication, is easy to change for different designs. The contact placement will be different for each type of circuit and the metals will vary with the conductivity type of the semiconductor layers. Fortunately, both electrochemical and vacuum deposition may be adapted to this requirement by using photoprocessing techniques. In the case of electroplating metals, a photoresist mask can be photographically formed directly on the unoxidized semiconductor. The resist mask then confines the current flow, and hence the deposition, to only those areas not masked. Vacuum deposition is done most conveniently through a metal mask that limits the deposited contacts to those areas not covered by the mask. Metal masks are etched from thin sheet stock using a photoresist coating to limit the etching. Here again, the only change in tooling for a new circuit is a new photographic negative.

After forming the junctions and making the contacts, the wafers may be separated into individual pieces having the required geometry. This geometry is largely determined by the desired current paths within the semiconductor and will vary from one circuit design to another. Sawing, or scribing and breaking the wafers, are logical methods of separation; but they are limited to straight-line geometry.

Ultrasonic cutting is possible, but it requires expensive tooling for design changes. The most satisfactory technique is to etch the units apart using photographic processing. In particular, a photoresist mask is applied as in the oxide removal procedure, but an etch that will attack the silicon is used. The wafer will be etched completely through where it is not protected by the resist, thus separating the units. At this step in the process, mesa areas are fabricated where desired by etching away unwanted diffused layers. The example in Fig. 6 illustrates the complexity of design that can be accomplished by photoetching techniques.

The individual units are now ready to have leads attached. For the bulk material, the leads are Kovar strips upon which the unit rests. For the diffused layers, lead wires are thermal-compression-bonded to the deposited and alloyed contacts. The Kovar strips are formed in a picture-frame assembly by photoetch techniques as illustrated in Fig. 7. Different circuits may require a different placement of the leads, and by photoetch fabrication the need for costly stamping dies is eliminated. A mounting base, which corresponds to the header of a conventional transistor, is formed by sandwiching the Kovar lead-frame between a ceramic and a Kovar ring. Conventional high-temperature glass-to-metal sealing techniques are used for this step. Some base pieces are loaded into a graphite fixture in preparation for firing. After firing, the leads are gold plated and the individual silicon units are placed in position. The units are then run through an alloying cycle to bond the semiconductor to the gold-plated Kovar. In a conventional mesa-plated Kovar this step would correspond to alloying the collector to the header.

Connections to the diffused layers are made by thermal compression bonding as shown in the opening photograph. Gold wires are positioned over the contacts, and a fine chisel is used to press each wire into the contact. Heat is simultaneously applied to raise the temperature to about 800 C, thus forming the bond. These connections are both mechanically strong and electrically reliable. Although thermal compression bonding requires considerable skill, it is a technique used in mesa transistor fabrication to make emitter and base connections.

The header to which the semiconductor pieces are fastened is also part of the package. All that remains is to attach the cover. Outline dimensions of the finished hermetically sealed package are shown in Fig. 8.

A variety of semiconductor networks can be manufactured using the processes described herein. With the stated restrictions on component values, those circuits that require large value resistors and capacitors, or any inductance, are not being offered at present. Typical circuits that have been fabricated and tested are shown in Fig. 9. In the case of logic elements, inverters and binary counter stages, the switching speeds frequently exceed the performance of a breadboard circuit with conventional components. This merely points out that when a transistor wafer is designed into a semiconductor block instead of mounting it on a header, the decreased collector capacitance and elimination of lead inductance en-
able a faster switching response.

In designing a semiconductor network, the material selection and diffusion layers are chosen to produce an optimum transistor structure for the particular circuit application. Since the transistor is an integral part of the circuit, exact operating conditions are known. Thus the transistor design may be accurately tailored to a particular application, which reduces the required number of compromises. This procedure may be used to improve the performance of a circuit or to maximize the yield of acceptable devices. For circuits requiring both transistors and diodes, the normal design procedure is still to optimize transistor performance.

The diode characteristic of an emitter-base junction usually differs from that of a collector-base junction. In particular, the emitter junction is relatively abrupt and has a low breakdown voltage, while the collector junction is more gradual and may have a high breakdown voltage. At the same time that each transistor junction is being formed by diffusion, any number of individual diodes with characteristics like either of the transistor junctions may be formed elsewhere on the wafer. Special diffusions also may be used on the same wafer to produce other devices.

As an example of the design procedure, consider the NOR circuit shown in Fig. 10A. The circuit has four diodes, three resistors, a capacitor and a transistor. All component values are within specified design limits; therefore, the circuit can be translated directly into a semiconductor network. It is desirable to change the lumped resistor-capacitor combination shown in the transistor base circuit to a distributed R-C network. Also, since the polarity of voltage applied to the capacitor does not change, a p-n junction-type capacitor may be used.

Although this circuit can be designed on a single wafer, in practice it is desirable to separate the resistors in the input circuit from the collector load resistor. When this is done, all the resistors are formed from two pieces of material. Typical values for $R_1$, $R_2$ and $R_3$ are 4,000, 10,000 and 2,000 ohms respectively. For 10 ohm-cm silicon, 2-mils thick, the required areas for these resistors will be 10 by 20 mils for $R_1$, 10 by 50 mils for $R_2$, and 10 by 10 mils for $R_3$.

These resistors may be arranged, along with the other necessary components, in the configuration shown in Fig. 10B. The starting wafer of n-type silicon forms the transistor collector region, all resistors and the cathode of each diode. A diffused p-layer is then used to form the transistor base region, the diode anodes and the capacitor overlying $R_1$. Next, an n-type diffusion is required for the transistor emitter region. These fabrication steps are applied to a large-area silicon wafer, typically 210 by 440 mils. After appropriate contacts are deposited, the wafer is separated into enough silicon bars to make 16 complete Nor circuits. This is a practical production process because it provides many units with identical characteristics. It is not an attempt to fabricate just one sample unit. The final step is to provide input and output connections and a few jumpers to connect some of the internal elements as shown in Fig. 10C. The latter connections are made with thermally bonded gold wires.

There are many alternate layouts which are theoretically possible for this design example. The proper selection of an optimum layout requires a thorough knowledge of available manufacturing techniques and their limitations. This job is performed by a semiconductor-network design engineer.

It is possible to design large digital systems using semiconductor networks that have already been fabricated and tested. However, before any large systems can be constructed, it will be necessary for the equipment manufacturer to develop methods of handling, testing and connecting devices an order of magnitude smaller than those to which he is accustomed. Tweezing handling and assembling under magnifica-
tion will be required if full advantage is to be taken of the small size of the individual units. Manufacturing techniques of this type, which are now routine in many branches of the electronics industry, will have to be adopted by the equipment manufacturer. Alternatively, the device manufacturer may be asked to subassemble a number of individual units into a larger package more easily handled.

Other new techniques will be required for testing the devices. Input and output conditions may be set, for instance, and the device subjected to varying environmental conditions to determine its acceptance or rejection. Only one set of tests will be necessary for each circuit, which greatly reduces the testing requirements. This type of testing will, however, require detailed knowledge of the performance actually needed in a given application.

For breadboard work with semiconductor networks, individual units are usually mounted on small etched-circuit cards. These may be inserted in test fixtures, or connected to form subsystems. Units mounted on two types of cards are shown in a photograph. For testing unmounted units, a more elaborate jig is required, as shown. The device to be tested is loaded on the slide and inserted in the fixture where the leads are contacted by 10 spring-loaded probes.

Because of the very small size of finished units, almost any form of interconnection will permit a worthwhile reduction in size and weight when compared to an assembly of conventional components. However, some effort is required to design a system where the interconnections require less volume than the semiconductor networks. One way to achieve this is to stack the units as shown in Fig. 11. The front cover illustrates the interconnection of semiconductor networks to form a unit of equipment. Connections between networks are provided by sheets of 2-mil-thick copper-clad Teflon. Because of close spacing between the leads, all of the wiring cannot be provided in a single plane. Multiple sheets are therefore used. Each required supply voltage is connected to a separate sheet that has a grid pattern with holes providing electrical and mechanical clearance for the leads. A lead may either pass straight through a sheet and be insulated from it, or be bent over and welded to provide an electrical connection. After all supply voltages have been connected, the top sheet is added to form the signal paths. If crossovers are necessary, a second signal sheet is used. When semiconductor networks are to be assembled in this manner, the designer should attempt to alternate the location of supply and signal leads on each package, thus increasing the spacing between adjacent terminals on the top sheet. Note that individual sheets may be used for shielding or as a ground plane. Also, this assembly technique may be useful for semiconductor network vhf applications, where the copper-clad Teflon sheets could become two-dimensional strip transmission lines.

Of course, other methods may be used for interconnection. In general, schemes which attempt to lay the units out flat will require considerably more space. A volume equal to that of the unit will be required for the lead connections, while the wiring will require still more volume. This additional volume will not be a total loss, however, if used to provide better heat transfer within the equipment.

The price of success in miniaturization is heat density. In particular, when electronic equipment is re-packaged and reduced in size without changing the circuits, the heat dissipation per unit volume significantly increases. A number of approaches to this problem are being pursued. First, semiconductor networks are designed for minimum power consumption. Second, each hermetically sealed package is shaped to have a high surface-area-to-volume ratio for efficient heat dissipation. Finally, since each semiconductor network occupies so little volume, conduction paths to heat sinks can easily be provided. For the stacked subassembly in Fig. 11, this may be done by placing between the units metal strips which are tied to heat sinks on the two open sides of the subassembly. Furthermore, the degrees of design freedom offered by semiconductor networks may produce new circuits that require much less power for operation.

The "standard" method for comparing packing efficiencies of different microelectronics approaches is to note the density of components per cubic foot. This is usually scaled up from one complete circuit or assembly of parts and often excludes the volume required for lead wires, interconnections, environmental protection and heat sinks. Considering just the heat dissipation problem, if we had one million components per cu ft and each component dissipated 10 mw, there would be 10 Kw of heat to be disposed of in each cubic foot. Obviously, the component density figure is not a realistic measure of the
number of components which could be connected and operated in a volume of 1 cu ft.

As each new microminiaturization idea is announced, the stated figure for component density is usually larger than any previously reported. At the present time, the highest number quoted is 100 million components per cu ft. These estimates of component density are not meaningful because the assumptions used in the calculation are never explained.

It may be of interest to “play the numbers game” for a Solid Circuit. The bare silicon bars in Fig. 10C have the equivalent of 9 components in a 2 by 10 by 80-mil space—this amounts to 9,700 million components per cu ft. When we allow space for the internal lead wires this number reduces to $260 \times 10^9$ parts per cu ft. Mounting this semiconductor network in the hermetically sealed package shown in Fig. 8, we have a density of $16 \times 10^9$ parts per cu ft. Finally, if we allow a volume for external connections equal to that of the package, we end up with 8 million components per cu ft. The reality of this last number has been demonstrated by the interconnection of 13 networks that contain the equivalent of 85 components in an operating subassembly that occupies 0.02 cu in. and weighs 1.5 gm. This amounts to 7.3 million components per cu ft.

There is apparently no satisfactory method for measuring the degree of microminiaturization. However, the application of semiconductor networks can produce equipment that is at least an order of magnitude smaller and lighter than equipment developed with other microminiaturization approaches.

Semiconductor networks combine the knowledge of semiconductor materials, established device fabrication techniques, and the logical approach to network analysis or synthesis that is familiar to all circuit designers. As a result, many types of Solid Circuit networks can be readily produced today. Although complete life test data is not available to support the claim that reliability has been significantly improved, the following reasons are proffered:

1. The purity level and order of lattice arrangement for the starting material is carefully controlled, whereas in other approaches many dissimilar materials of varying or unknown degrees of purity are used.

2. By using a single material, up to 80 percent of the connections required for a conventional circuit are eliminated. The various regions which form circuit elements are continuous within the one bulk material. This minimizes the mismatch in thermal expansion coefficients which usually is the cause of catastrophic failures. Besides reducing the number of solder joints between lead wires on individual components, we are also reducing the number of junctions where each lead wire is attached to the actual circuit element (such as where a resistor lead is bonded to the carbon rod or metal film; or where a capacitor lead is attached to the metal foil or silvered-mica plate). The use of metal contacts alloyed into the semiconductor also reduces the interfaces between dissimilar materials.

3. The small number of required process steps permit accurate process controls to be economically applied. All the fabrication steps are performed in one plant and on one production line; therefore, complete statistical methodology will be used.

4. Since the entire circuit is hermetically sealed, both active and passive elements are protected against environmental conditions.

5. Because of the very small mass, semiconductor networks are difficult to damage by shock or vibration.

Today, semiconductor networks are not commercially available in all types of circuits. Many of these circuits were developed as a compromise between the electrical characteristics and cost of conventional components, thus they may not be optimum for the different electrical characteristics and economic factors of the Solid Circuit. Nevertheless, this approach to microelectronics is adequate in many cases. For example, with the large number of repetitive functions in present-day digital computer circuits, complete systems can be constructed with only a few semiconductor network building blocks. The most attractive semiconductor networks of the future may have no real counterpart using conventional components, or they may, in retrospect, be considered impractical for the present state of technology.

Remote Tv Control

BY BLANKING-INTERVAL PULSES

Local program matter is keyed-in by a remote transmitter which sends control pulses during the vertical blanking interval. Control signals are decoded at subsidiary stations where they govern programming.

By KOMEI KAZAMA and TAKAYOSHI, ISHINO,
Japan Broadcasting Corporation, Osaka, Japan.

This system comprises a special transmitter to generate the control pulses, and a receiver at each station, to be controlled, to decode these pulses and translate them into the appropriate switching actions. Six control channels are available, permitting transmission of six different instructions. Thus, the control system can introduce special program matter such as a film projector, outside broadcast, weather forecast, or other special effects. Extending this principle, control pulses received by remote booster stations can turn the transmitter off or on, or initiate other operations peculiar to that station.

According to the Japan Television Technical Standards, the vertical blanking interval corresponds in duration to twenty-one horizontal scans. Although the picture is not shown during this blanking interval, the horizontal synchronizing pulses continue to be transmitted to preserve system synchronism. The period of the first fifteen sweeps is allotted to special purposes, leaving a final period of six sweeps during which control signals can be broadcast.

The actual control signal is transmitted in the interval between horizontal sync pulses. Since there are six such unallocated intervals, six control channels are available. At the receiving station, the control signals are passed through special circuits where they energize switching relays to carry out the operations mentioned above.

The main function of the transmitting section of the control system is to insure that the control pulses are generated in the correct time interval—or channel. Furthermore, these pulses must occur at a fixed period within that chosen channel, that is, at a definite time-delay after the preceding horizontal synchronizing pulse. Channel selection is provided by a 6-position switch that sets the delay (500 to 2,000 µsec) of the channel-selecting monostable multivibrator MV1 (Fig. 1). This multivibrator is triggered at the start of the vertical blanking interval and produces an output pulse that determines in which channel the control pulse shall be transmitted. Thereafter, horizontal sync pulses take over the timing to provide accurate synchronization of the final transmitted pulse.

Channel five will be discussed so that the circuit description can be specific rather than general.

The transmitter block diagram is shown in Fig. 1, and its associated waveforms in Fig. 2A. The vertical blanking waveform triggers channel selecting multivibrator MV1 and the multivibrator returns to its stable OFF condition after the preselected delay. Return to the OFF state is shown in Fig. 2A at time A, just before the sync pulse that marks the beginning of the fifth channel interval.

After amplification, differentiation, clipping and further amplification, the output from the channel-selecting multivibrator provides a positive going trigger for bistable multivibrator MV2. This bistable circuit is turned to its ON state.

Thus far, a pulse has been generated that occurs shortly before the selected channel interval. Since the actual control pulse must be transmitted midway (approximately) between transmissions of sync pulses, further delay is necessary.

Shortly after MV 2 is turned ON by the output from the channel-selecting multivibrator, the (next)
sync pulse is generated by the picture control circuits. This sync pulse is amplified and shaped, then used to return the MV2 to its OFF state. In going OFF, multivibrator MV2 produces a positive-going output coincident with the leading edge of the sync pulse shown at B in Fig. 2A.

The output at B from the bistable multivibrator is amplified and shaped and turns a monostable delay multivibrator, MV3, ON. This multivibrator is timed to return to its OFF state about 10 to 20 microseconds after being turned ON, so its output will occur between the correct pair of sync pulses at time C.

When MV3 returns to its OFF state it produces a positive output. After amplification, the MV3 output pulse is differentiated and clipped to provide a positive trigger for the final pulse generator circuit.

The final pulse generator, MV4, is a monostable multivibrator having an output adjustable between the limits of 10 and 20 microseconds. When triggered by MV3 it develops the controlling pulse shown at CD in Fig. 2A. After amplification, this final modulating pulse is fed to the cathode of the main-line video amplifier, causing control pulses to be broadcast with picture signals.

The control system receivers are located wherever they are required to introduce program changes at the command of the main transmitting station. The receiver interprets the transmitted signal and carries out the preselected switching functions by magnetic relays.

The receiver decodes the incoming control pulse by generating a gating waveform during the channel interval that is being interrogated. If, or when, the control pulses occur in this same channel interval, they are passed through the gating circuit, and ultimately operate the switching relays already mentioned.

As in the transmitting sections, the vertical blanking pulse triggers a channel-selecting monostable multivibrator (MV1, Fig. 3A) whose timing is set by the channel selector

FIG. 2—Waveforms of the transmitting section of the control system (A); photograph of the composite video and control waveform (B); waveforms leading to the decoding of the control pulse in the receiver (C)
switch. Receiver waveforms are shown in Fig. 2C. In the receiver, however, unlike in the transmitter, the delay period is adjusted so that the trailing edge of the channel-selecting waveform arrives just after the sync pulse that marks the beginning of the selected channel. (In the transmitter section it occurs just before this sync pulse.)

Output from MV1 triggers bistable multivibrator MV2, turning this to its ON state. Output from MV2, whose leading edge is shown at P in Fig. 2C, provides the gating waveform. At the end of the fifth channel interval, MV2 is returned to its OFF state by the following sync pulse. The bistable multivibrator is ON from shortly after the sync pulse at the beginning of the scan until the arrival of the pulse at the end of it. In doing so, it adequately spans the fifth channel interval.

The positive going waveform from the gate pulse shaper amplifier is fed to the suppressor grid of the gate (Fig 3A and B). The video signal input, containing the control pulse, is fed to the control grid of the gate. If the gate and control pulses occur in the same interval, that is, in the same channel, the control pulse will be amplified by the gate tube and appear at its anode as a negative-going pulse.

Assuming that the gate and control pulses coincide, the amplified output from the gate pentode is fed to the cathode of a pulse generating binary circuit. This binary circuit converts a pulse of some 10 to 20 microseconds width to a much wider pulse. Output from the binary is fed to a rectifier. The positive output from this rectifier overcomes the cathode bias on the relay driver, causing it to conduct, thereby energizing the relay in its anode circuit.

The pentode-driven main relay operates auxiliary relays, which perform the required switching functions.

Provision is made for the local booster station to pass on the control signal even when this station is sending out its own local program. This is done by feeding the amplified output from the gating circuit to the local stations, video amplifier, where it inserts the control pulse in the transmitted output.

In designing this device, the authors are indebted to many friends of JOBK-TV for their friendliness and cooperation, and are especially grateful to Mr. Kajiki, Chief of TV Technical Section, and to Mr. Osugi, Chief of TV Control Division, for their guidance and encouragement.

INCREASING FLEXIBILITY

The above description has shown how this system switches between remote and local-station broadcast.

Perhaps additional modifications might permit system to have even more flexible control over a local station's program matter.

Suppose the control station wants to switch all local stations that are on channel 5 to field-pickup transmission, then local broadcast, and then switch back to remote broadcast.

Provision could be made at the transmitter to send a control pulse at a 50-cps rate, rather than a 60-cps rate. Additional circuits, including a 50-cps filter, at the receiver could switch a control relay that would switch the local station to field pickup during the time the control pulse is being transmitted at a 50-cps rate. When the control transmitter starts sending its control pulse at a 60-cps rate, it switches local stations to local broadcast. When the control transmission stops, local stations switch back to remote broadcast.

**Switching functions (A); Only the decoding portion of the receiver circuit (B) differs markedly from the transmitter circuit.**
Selecting R-C Values For Filters characterized by no output at infinite frequency or at zero frequency can be realized with R-C circuit configuration. Symmetry of network voltage transfer function allows R-C component values to be determined by coefficient-matching technique. Problems of weight, small dynamic range and sensitivity to hum are definite limitations to the physical realization of electrical filters using passive R-L-C components only. Moreover, specifications that call for very low filter cutoff frequencies make design with inductance in the circuit especially impractical. A remedy for these difficulties lies in the use of so-called active R-C networks.

An active R-C network has no need of inductance as a circuit parameter; instead, resistors, capacitors and vacuum tubes (or transistors) are arranged in suitable feedback configurations for filter design realization. Many useful applications can be found in the literature. Furthermore, several manufacturers now market adjust-

In spite of the progress already made in the field of active filter design, there is still needless complexity associated with active R-C filter design. This article describes a novel R-C circuit configuration that affords easy realization of a useful class of filters. These filters are characterized by zeros of transmission (no output) at infinite frequency (low-pass type) or at zero frequency (high-pass type). Bandpass and band-rejection filters can also be realized by proper combination of low- and high-pass sections.

The usefulness of the basic configuration results from the symmetry of the network voltage transfer function (ratio of the Laplace transform of output voltage to the Laplace transform of input voltage), allowing R-C component values to be readily determined by the technique of coefficient matching. Also important is the fact that, for most designs, interstage buffering can be accomplished by simple cathode or emitter followers.

Specifications for a filter design are usually given in terms of bandwidth, center frequency (for a bandpass filter), allowable ripple of the frequency characteristic in both pass and stop bands, and, rate of attenuation beyond the cutoff frequency. (Cutoff is usually the frequency at which the filter output is 3 db below the normal pass band level.) Sometimes the filter transient response is a critical factor and additional specifications must be given to define percent overshoot, rise time and settling time.

Once the necessary transfer function has been determined, the designer has the choice of using either passive R-L-C or active R-C networks for realization. While the purpose of this article is to describe a novel, active R-C circuit configuration for easy realization of filter transfer functions, it is not feasible to discuss the determination of a transfer function from a given set of specifications. For this reason, a particular set of filter functions, widely used in engineering practice, will form the basis for the following discussion of active R-C realization. This set, representing the Butterworth filter functions, is characterized by a frequency response that is maximally flat within the pass band with an attenuation rate beyond the cutoff point of 6 db per octave per section. In addition, the transient response of a Butterworth filter is usually satisfactory for most applications, although the percent overshoot becomes greater as the order (number of sections) of the filter increases.

In Table I, Butterworth low-pass filter transfer functions are listed for orders through \( n = 5 \). The filter bandwidth, \( B \), is given in radians per second. Shown in Fig. 1 are the corresponding frequency response curves found from the filter transfer function by setting \( s = j\omega \). (The complex frequency variable of the Laplace transform is \( s = \sigma + j\omega \).)

Easy realization of filter transfer functions like those listed in Table I can be accomplished with the active R-C network chains shown in Fig. 2. The \( +1 \) symbols are unity-gain buffer stages; for analysis it can be assumed that the input impedance is infinite and the output impedance is zero. The distinguishing topological feature of the network is the "chaining" of feedback elements (capacitors in the low-pass case) from the output of one stage to the input of the preceding one, except for the last section where the feedback element is grounded.

Network transfer functions can be derived in each case by applying Kirchoff's current law (\( \Sigma I = 0 \)) to each independent node and solving the resulting set of simultaneous equations. Figure 2 includes the voltage transfer functions for \( n = \)
1, 2, 3 and the general \( n \)th order configuration where \( s \) is the complex variable \( (s = \sigma + j\omega) \) and \( \omega_n \) is the frequency constant for the \( k \)th section \( (\alpha_n = 1/R, C) \). It is important to notice the basic symmetry of the transfer function denominators; that is, the fact that the frequency constants are introduced one by one, from left to right. It is this fact that allows for easy filter realization, which is done merely by matching the denominator coefficients of the circuits of Fig. 2 to corresponding coefficients of the desired filter transfer functions of the same order (as in Table 1). For instance, a low-pass filter having a desired transfer function

\[ \frac{E_0}{E_1} = \frac{K}{s^n + a_1 s^{n-1} + a_2 s^{n-2} + \ldots + a_n} \]

(1)

can be realized with the \( n \)th order chain of Fig. 2. Transfer function, repeated here for convenience, is

\[ \frac{E_n}{E_1} = \frac{\prod_{j=1}^{n} \omega_j}{s^n + \omega_n s^{n-1} + \omega_n^2 s^{n-2} + \ldots + \omega_n^n} \]

(2)

where the \( \prod \) indicates a continued product \( \left( \prod_{j=1}^{k} \omega_j = \omega_1 \omega_2 \ldots \omega_k \right) \). The frequency constants can now be determined by equating corresponding denominator coefficients in Eq. (1) and (2); thus, \( \omega_1 = \omega_n \), \( \omega_2 = a_1 \omega_n \), \( \omega_3 = a_2 \omega_n \), \ldots, \( \omega_n = a_n \omega_n \).

The designer can now choose the value of either \( R \) or \( C \) for a section while determining the other from the relation \( \omega_n = 1/R, C \). In addition, it is seen that, ideally, the insertion loss in the pass band is 0 db for the R-C chain. One design consideration is to negate the effect of finite follower input and output impedance by proper choice of section impedance level. This is hardly a design restriction, however.

The procedure just outlined has been applied to the realization of a fifth-order Butterworth low-pass filter with cutoff frequency at 25 cps. Several identical units were built for the purpose of filtering the output channels of a narrow-band speech-compression system. A simple diagram for realization of the fifth-order filter is shown in Fig. 3A. Design values were determined by matching coefficients of the transfer function for \( n = 5 \) in the first column of Table I to those for the fifth-order R-C chain transfer function to obtain \( \omega_n = 3.236, C = 5.236 B, \) and so forth. This yields \( \omega_5 = 5.236B/3.236, \omega_n = B_n C = 3.236B/5.236, \omega_n = B/3.236, \) and, finally, \( C = 0.309/BR, C = 0.618/BR, C = 1/BR, C = 1.62/BR, \) and \( C = 3.24/BR \).

The final filter realization is shown in the circuit diagram of Fig. 3B, for \( B = 25 \times 2\pi \) radians per second and \( R = 100,000 \) ohms. Even with all resistor values set equal, the spread of the \( C \) values is only about ten to one. A frequency response characteristic for the circuit is shown in Fig. 3C, along with the time response to a 5-cps square wave. Although R-C component values were adjusted to \( \pm 1 \) percent, the cathode follower gains were slightly less than unity. Even so, the average cutoff frequency for those units tested was only 4 percent below design value of 25 cps. The average insertion loss in the pass band was 3 db.

High-pass filters (zeros of transmission at zero frequency) can also be realized using the techniques outlined thus far. The basic active R-C configurations of Fig. 2 need to be modified only to the extent of interchanging the resistors and capacitors. The transfer functions for the high-pass forms exhibit a sort of reverse symmetry; for example, for the \( n \)th order configuration.

</table>

MAY 13, 1960 • electronics
As an illustration of the alternate procedure, the fifth-order Butterworth low-pass filter derived previously will be redesigned. Shown in Fig. 4 is the necessary combination of first and second-order chains for realizing a fifth-order filter. The resulting transfer function, shown in Fig. 4, can be matched to the transfer function for n = 5 in the second column of Table I to obtain \( \omega_1 = B, \omega_2 = 0.618B, \omega_{30} = B, \omega_4 = 1.618B \) and \( \omega_{30} = B' \). This yields \( \omega_1 = B/0.618, \omega_2 = B/1.618, \) and, finally, \( C = 1/BR, C_1 = 1.62/BR, C_2 = 0.618/BR, C_3 = 0.618/BR, \) and \( C_4 = 1.62/BR. \)

When all resistor values are set equal, the spread of capacitor values is only three to one. The disadvantage of this method, however, is the necessity for factoring the desired transfer function denominator, which is a tedious process for a high-order filter.

An analysis of the circuit configurations given in Fig. 2 for buffer stages of gain K shows that the transfer functions are modified as indicated in Table II. From Table II, it is seen that the effect of nonunity gain buffers appears in a predictable fashion and can be deduced for any number of stages.

It was found that the use of simple cathode followers (12AX7's) in the design of the fifth-order Butterworth low-pass filter contributed less than 4 percent error in cutoff frequency and much less than that in attenuation rate beyond the cutoff point. It would be expected, though, that the gain-stability problem would be more critical in the case of a bandpass design. However, if specifications are tight, it is possible to employ augmented cathode followers to achieve stable unity-gain buffer stages.

This work was originally done under contract with AFCRC. The author wishes to thank S. H. Chang and R. E. Scott for their encouragement and helpful criticism.

Using Ground-Control Radar
TO IMPROVE FLIGHT SIMULATION

By PAUL W. STAIGER,
Field Service Engineer, Melpar, Inc., Falls Church, Va.

A PILOT TRAINING in a flight simulator learns to fly by instruments and his instruction includes making GCI (Ground Controlled Intercept) interceptions of enemy aircraft. However, he doesn’t normally come under the control of a GCI director until he flies an aircraft. The system to be described ties an F-86 Flight Simulator into standard operational GCI equipment, the simulator being over two miles away from the GCI site.

As in the normal case, a flight-interception problem is set up in the simulator by an instructor. Interceptor and target positions are recorded by pens on a plotting board which the pilot does not see. (Fig. 1). The lower left corner of the plotting board is the reference point, the GCI site, from which the pens may record distances up to 150 miles in north and east directions from the GCI site.

Interceptor and target-position computers convert information from the plotting board into range and azimuth data. Since the target computer is the same as the interceptor computer, only the interceptor computer is shown in Fig. 1 and only it will be discussed.

Telephone lines between GCI site and interceptor carry trigger pulses from the GCI radar to the interceptor computer. Ensuing range-echo pulses from the computer are gated to the GCI only when GCI-radar-antenna azimuth is the same as the azimuth of the interceptor. Thus, the range echo pulse provides azimuth information and range.

The GCI director sees interceptor and target positions on his scope, and uses the data-link computer to calculate the interception solution. A uhf link carries steering information to the pilot; this information is either voice instruction or instrument display. The uhf link also enables the GCI director and pilot to discuss a problem.

As indicated in Fig. 2, a computer sums voltages that are determined by the positions of power, aileron, elevator, and rudder con-
The total velocity (amplitude) and heading (phase) go to resolver \( B_r \), which resolves velocity into north and east components.

North and east servos (MOT 1 and 2) drive the interceptor pen in the required direction by pulleys and spools. The rate at which the pen drives up or down (north or south) and right or left (east or west) depends upon the amplitude and phase of the velocity input to resolver \( B_r \).

The north and east servos each drive potentiometers indexed for zero output voltage when the pen is at the bottom of the plotting board and the carriage is at the left side. Output of these potentiometers \( (R_x \) and \( R_y \)) represents the distance that the interceptor pen is north east of the GCI reference point.

Modification of the simulator begins at this point, with the application of potentiometer outputs to the stator windings of resolver \( B_r \).

The voltage induced in rotor winding \( X \), is fed through a motor amplifier to MOT 3, which positions \( X \), to null out the induced voltage. The arm of \( R_x \) is also positioned by MOT 3. Null positions of rotor winding \( X \), and the voltage at the arm of \( R_x \), represent interceptor bearing from GCI. After the rotor of \( B_r \), has reached a null position, the voltage induced in rotor winding \( X \), represents the vectorial sum of the voltages corresponding to the interceptor north and east positions.

The voltage from \( X \), is fed through a motor amplifier to MOT 4, which positions the arms of \( R_x \) and \( R_y \). Motor 4 rotates until the feedback voltage from \( R_x \) nulls out the voltage from rotor winding \( X \). This action also positions the arm of \( R_y \), whose voltage corresponds to the interceptor range from GCI.

The master trigger pulses from GCI go to isolation amplifier 1, which is coupled to a sweep multivibrator, \( MV \). Upon application of the master trigger, \( MV \), flips, triggering the sweep generator. The sweep's sawtooth output is linear, and allows the amplifier to change to maximum, charges to \(+250 \, \text{V d-c} \) in \( 2.460 \, \mu\text{sec} \) (200 miles). A sweep stopper circuit receives this positive-going sawtooth.

Potentiometer \( R_e \) has \( 250 \, \text{V d-c} \) across its terminals; since its output is directly proportional to range, zero range is equivalent to zero \( \text{V d-c} \) and a 200-mile range corresponds to \(+250 \, \text{V d-c} \). When the sawtooth voltage, which represents the GCI radar sweep range, and the output of \( R_e \), which represents the interceptor range from GCI, become equal, the sweep stopper triggers. Sweep multivibrator \( MV \), now flops, stopping the sweep.

The trailing edge of each square wave output of \( MV \), occurs at the time that corresponds to the interceptor range echo. By applying this square wave to a differentiating circuit, and then to a shaping amplifier, the leading edge is removed and the trailing edge shaped. This shaped range pulse is then applied to amplifier 2 of a radar echo-gating circuit. Amplifier 2 is normally biased at cutoff by a cutoff control.

The echo-gating circuit prevents the interceptor range echo from appearing on the GCI scopes as a continuous ring. A range echo goes to GCI only when the GCI antenna bearing agrees with the bearing of the interceptor pen to the GCI reference point on the plotting board.

Since the GCI antenna bearing must be available at the simulator site, synchronous voltage is transmitted from the GCI antenna-drive motor over telephone lines to a repeater servo at the simulator site. Potentiometer \( R_e \) is coupled to this servo and used to represent the bearing of the GCI antenna and sweep.

The antenna-bearing voltage from \( R_e \), goes to one end of \( T_e \); the other end of \( T_e \), receives the interceptor-bearing voltage from \( R_e \). When the voltage from \( R_e \), is equal in amplitude and phase to the voltage from \( R_e \), no voltage is induced in the secondary of \( T_e \). Absence of this voltage causes the cutoff control to remove the cutoff voltage applied to amplifier 2, permitting the interceptor radar echo to be amplified by amplifier 2 and to go to the GCI.

The author acknowledges the assistance of R. F. Rundell in the preparation of this manuscript. The U.S. Air Force, Moody A. F. Base, Georgia, sponsored the work described in this article.
GAIN-PHASE MEASUREMENTS IN Feedback Amplifiers

Test circuits show how to accurately measure gain and phase angle characteristics of closed-loop amplifiers

By M. SCHREIBMAN
Industrial Test Equipment Co.,
New York, N. Y.

PRECISE MEASUREMENT of gain and phase angle characteristics is an important consideration in the development of synchro, computer, resolver and other closed-loop amplifiers. Usually the function of these amplifiers is to provide a constant overall gain and a phase shift close to zero or 180 degrees. Often the precision called for in both gain and phase shift makes it impossible to use ordinary methods of measurement and so it is necessary to use special measuring techniques.

A particular, but often used type of closed-loop amplifier, is that in which unity gain and zero phase shift are simultaneously required. If such an amplifier could be built perfectly and be free of distortions, the output signal would be identical to that of the input.

If the output of this ideal amplifier were connected in a series opposing manner to the input of the amplifier, as illustrated in Fig. 1A, the difference voltage appearing at the input to the detector would be zero. However, since a distortionless amplifier is not feasible, there will generally be a fair amount of distortion contained in the difference voltage. Also, if the amplifier does not maintain a perfect unity gain, there will be an in-phase voltage component appearing in the difference voltage. Similarly, if the amplifier does not maintain a perfect zero-degree phase shift, there will be an additional quadrature voltage component appearing in the difference voltage.

For the small angles considered, these differences in in-phase and quadrature components are directly proportional to the respective errors in amplitude ratio and phase shift of the amplifier. If the detector shown in Fig. 1A could measure the in-phase and quadrature components of the difference voltage independently, the error in amplitude ratio and total phase shift could then be read directly.

To illustrate this application, consider an amplifier, connected as shown in Fig. 1A, which has a nominal gain of one and a nominal phase shift of zero degrees. To add realism, assume the noise and harmonic distortion is 0.1 percent.

When a signal of 10 v is applied to the input of the amplifier, the difference voltage components as read on the detector are +10 mv in phase and +17 mv quadrature. The actual ratio of output to input of the amplifier is 10.01 v/10 v or 1.001, the phase shift is 17 mv/10 v or 0.0017 radians (0.1 degrees), and the magnitude of the noise and harmonic distortion components appearing in the difference voltage is 10 mv. Since this is the same order of magnitude as the fundamental components being measured, it would be necessary for the detector to reject these undesirable signals to a point where the measurement accuracy is not affected.

The interesting feature of this type of measurement is its accuracy. All errors in measurement apply only to the difference voltages. For example, if in the preceding example the accuracy of measurement of the difference component was limited to 10 percent, the maximum error in the overall measurement would be 0.01 percent for gain and 0.01 degree for phase shift.

If the output of the amplifier is nominally 180 degrees out-of-phase with the input and a common ground exists between the two, the circuit of Fig. 1B can be used. In this circuit, precision matched resistors R1 and R2 are used to derive the difference voltage. The two resistors used should be of the same type so that their reactances will be matched. The value of the resistors should be as low as possible, but not low enough to load down the amplifier. Generally, 100,000 ohm to 500,000 ohm resistors are suitable.

If the input and output of the amplifier have a common ground and the nominal phase shift is zero degrees, then the circuit configurations shown in parts C and D of Fig. 1 will apply. In Fig. 1C, isolation transformer T is used to transfer the difference voltage to the detector. This arrangement permits grounding of the detector circuit, a condition which should always be adhered to when measuring small difference voltages. The transformers used in this case should have a low phase shift and a known transformation ratio. However, these characteristics are not critical as they will have only a
provide better picture quality than ever previously attained.

second order effect on the accuracy of the measurement. Since it is possible for the transformer to load the output of the amplifier, the circuit in Fig. 1C should only be used when the output impedance of the amplifier is low, that is, 100 ohms or less.

If the output impedance of the amplifier is high, the circuit of Fig. 1D can be used. Here, the transformer does not load the amplifier, but the errors in the transformer will add directly to the errors of the measurement. Thus, a transformer should be used which has zero phase shift and a precise 1:1 transformation ratio. A transformer with characteristics which closely approximate these requirements can be used if the characteristics are precisely known. The transformer error can then be subtracted from the measurements.

Another method of deriving the difference voltage is to use an electronic difference amplifier as shown in Fig. 1E. Only the highest quality difference amplifier can be used because it must resolve accurately a difference voltage which may be in the order of 0.01 percent of the input voltages. Any errors in the difference amplifiers will add directly to the measurement error.

In some cases the required amplifier gain may be greater or less than unity. Since the method which has been described is perfectly general, it will apply to these cases as well. Parts F through J of Fig. 1 illustrate typical circuits for measuring amplifiers with gains of other than unity.

In Fig. 1F, precision resistors $R_1$ and $R_2$ are selected so that the ratio $R_2/(R_1 + R_2)$ is equal to the nominal gain of the amplifier. In this case, of course, it would be some value less than one. Care should be taken to select resistors having a minimum capacitive or inductive reactance in order to prevent phase shifts in the attenuator.

In Fig. 1G, the attenuator is placed across the output. In this case gains greater than one can be measured and the resistors are chosen so that $R_2/(R_1 + R_2)$ is equal to the inverse of the gain of the amplifier. The sum of the resistances of $R_1$ and $R_2$ should be high enough not to change the amplifier characteristics because of their loading effect.

Figure 1H is essentially the same as Fig. 1B. This circuit can be used equally well for amplifiers with gains of greater or less than unity. The ratio of $R_1:R_2$ should be the same as the nominal gain of the amplifier.

The circuit of Fig. 1I is used for amplifiers with gains of less than unity and where a common ground exists between input and output. The attenuator resistors are selected in the same manner as for the circuit of Fig. 1F.

The circuit configuration in Fig. 1J utilizes a precision transformer for measurements of amplifiers with gains of greater or less than unity. The transformation ratio of the transformer should be equal to the inverse of the nominal gain of the amplifier.

**FIG. 1**—Test connection for measuring quadrature components and phase shift of amplifiers with unit gain (A through E) and gain other than unity (F through J)
Why rely on “roundness”? Cambion® guarantees concentricity

So much can go wrong when coil forms are even slightly out-of-round that it pays to make certain they’re concentric! CAMBION Ceramic Coil Forms are manufactured to extremely close limits of concentricity. They wind evenly and easily. Finished coils tune smoothly and precisely with no binding of slug. CAMBION Coil Forms are given many other rigorous quality control checks at every step of manufacture: moisture-resistance test, plating check of all significant surfaces, etc. Result: guaranteed quality . . . the best basis for successful winding, installation, tuning and performance.

All CAMBION Components follow a careful quality control program because the quality of any component of course limits its reliability. And the ever-increasing importance of reliability is apparent on all sides. Take one type of missile with 32,000 components, all interdependent. If each individual component had a reliability factor of .99999, it would mean failure of 1 out of 4 such missiles. Success demands quality control of all components. And quality control is the reason why all CAMBION Components meet or surpass Government specifications.

Synchronous Pump Ups Noise Figure

Fifty-percent increase in effective range of a coho MTI radar was achieved in recent tests at Rome Air Development Center. An electron-beam parametric amplifier operated in a synchronous pumping mode improved receiver sensitivity as much as a five-fold increase in transmitted power.

The equipment was developed by Zenith Radio Corp., and application of synchronous pumping was originally suggested by K. G. Eakin of RADC. The electron-beam parametric amplifier was developed by a research team headed by R. Adler, associate director of research at Zenith, in association with G. Wade, Stanford Electronics Laboratory.

Synchronous Pumping

Conventionally beam-type parametric amplifiers are operated with a pump frequency nearly, but not exactly, twice signal frequency. It had been believed that a pump frequency exactly double the signal frequency (synchronous pumping) would impair performance. It was assumed that noise picked up by the idler channel would be injected into the signal channel. A slight change in frequency was felt necessary to stay outside the passband.

Tests of the equipment confirmed that synchronous pumping permits full use of the low-noise potential of the amplifier in high-performance radars. Minimum detectable signal measurements were made of the bipolar and unipolar video output of the MTI synchronous detector and the video output of the normal linear detector. With synchronous pumping, average improvement in sensitivity was 10 db on the synchronous detector channel and 9 db on the linear detector channel. These figures exceeded the expected 7-db improvement, probably because effective antenna temperature was less than 290 K.

The photographs compare A-scope displays of synchronous and linear detector outputs with non-synchronous and synchronous pumping. In each case, i-f gain was adjusted to equalize noise levels. For nonsynchronous pumping, an independent signal generator replaced the synchronous pump generator.

The quadrupole amplifier was inserted directly between duplexer and mixer of the existing radar. Since the tube is unidirectional, no circulator or isolator is needed. Input and output impedances are resistive and independent of gain. The existing impedance match is not disturbed nor is stability of the receiving system impaired.

Frequency response of the amplifier used is flat over about 80 Mc centered at 1,300 Mc. It is normally operated at about 20 db gain, although gain can be adjusted from —1 db to more than 30 db by varying pump power.

Bandpass is independent of gain, and at 20-db gain there is only about 1.3 db change in gain for a 10 percent change in pump power.

The broadband noise figure of the amplifier tube is 1.3 db. Without the amplifier, radar system noise figure was 8.5 db; with the amplifier, system noise figure was 1.6 db. No allowance for idler channel effects need be made with synchronous pumping.

Application to Coho

The particular tube used in the tests was developed by R. L. Cohoon at Zenith. In a coho MTI radar system using the new amplifier and synchronous pumping, it is possible to derive a synchronous signal for pumping the parametric amplifier so that signal and idler coincide exactly.

Under these conditions, signal and idler add coherently in the detector and cooperate in producing the output. Since the coherence applies to noise inputs and to the desired echoes alike, no reduction in signal-to-noise ratio results from the presence of the idler channel. Therefore performance attained is characterized by the so-called broadband noise figure of the parametric amplifier, which can be very low.

The pumping signal is generated by doubling the stable (1,324 Mc) and coho (30 Mc) signals available in the radar and mixing the resulting frequencies. An amplifier and filter select the difference (2,588 Mc), which is exactly twice transmitter frequency (1,294 Mc), and apply it through a phase shifter to the quadrupole pumping structure. With a linear detector, pump phase is of no importance, but an optimum phase exists when MTI is used.

Improvement in sensitivity applies to both the MTI channel using the synchronous detector and to the normal channel with a linear detector because both signal and idler

Transponder Electronics

The transponder uses 40 transistors and diodes. The r-f package contains a filter, duplexer, mixer, 30-Mc i-f amplifier, second detector, local oscillator and transmitter. A second package contains the video bandwidth filter, video amplifier, pulse-width discriminator, time-delay pulse generator, modulator and batteries.
components of the target echo are present within the passband of the i-f amplifier. Under these conditions, precise coherence is no longer necessary to obtain performance corresponding to the broadband noise figure; synchronization of the pumping source merely ensures that the idler channel will be accepted by the subsequent system.

Tiros I Tracked From Horizon to Horizon

ACQUIRING information to compute orbit parameters for Tiros I was greatly aided by a uhf transponder beacon. Installing the beacon in the third stage permitted tracking beyond its skin-track capability. The quality of radar data was improved and horizon-to-horizon coverage was provided.

The Millstone Hill Radar Observatory, Westford, Mass., and operated by MIT Lincoln Laboratory for USAF, has been tracking many Cape Canaveral launchings. Because of the highly sensitive radar receiver at this site, an output of only 10 mw was required from the beacon transmitter. This signal enabled Tiros I to be tracked 1,700 nautical miles to the radar horizon from Millstone Hill.

The beacon was developed from conception to breadboard installation in six weeks. It was built under subcontract to Texas Instruments Inc. with collaboration of Lincoln Laboratory in the engineering development. The system was first successfully tested in the ill-fated Transit I last September.

Tracking Data

As a member of the NASA team for this operation, with the Air Force Ballistic Missile Division and Space Technology Laboratories, Millstone tracked the launch phase and two subsequent passes. The tracking permitted observation of stage separation, spin rate and orbit injection parameters. Processed tracking data were dispatched by Space Net TWX to STL and the NASA Computation and Control Center in Washington within minutes after the end of each run. The Millstone data from the three sets of observations, a little more than

Micro-Energy Switch for Logic Circuits

ONE OF THE PROBLEMS encountered in high-speed computer logic circuits is to find high-speed switching components that will perform at much lower energy levels.

With the exceedingly high packing densities now demanded in microminiaturized equipment, power dissipation levels can cause an intolerable amount of heating. And the search is on for high-speed switching transistors that can be optimized for operation at low collector voltages and low collector currents.

Further, it has been recognized for some time that, for maximum reliability, transistor power dissipation should be held to an absolute minimum.

Last week at the Western Joint Computer Conference in San Francisco, engineers were offered a practical solution to these problems. In a technical symposium aimed at designed engineers, Philco men pointed out the capabilities and implications of switches they are now developing that promise to operate at the repetition rates of today's most modern high-speed switching transistors, but can do this in circuits that operate at much lower power levels. And Philco feels that this micro-energy concept is an important step in scaling down the size of high-speed highly reliable logic circuits. The company visualizes a whole family of perhaps ten or twelve transistors for this purpose, based on the MADT construction.*

In a conventional transistor, the factor that limits operation at low energy levels is the junction capabilities. By using well chosen resistivity profiles of the MADT, and by improved geometry and advanced metallurgy, the Philco design makes it possible to design high-speed logic circuits that operate with an overall power consumption of less than one-third that of conventional transistors. And micro-energy switches now in de-

*Trademark. Philco Corporation, for Micro Alloy Diffused-Base Transistor

Penn., features an emitter transition capacity less than one-third that of presently available modern high-speed switching transistors, a collector capacity approximately one-half that of modern switching units, a gain-bandwidth product specified greater than 125 Mc at a collector voltage of 1 v, a collector current of 1 ma, and a beta characteristic which optimizes at approximately 1 ma. The minimum saturation current gain of the transistor is 25 at a collector current of 2 ma.

This first switch will operate at pulse rates in excess of 10 Mc when switching collector currents as small as 1 ma from collector supply voltages as small as 1 v. A low cost germanium device with a maximum temperature rating of 100 C, the switch has been designed for automated production and will be available in prototype design quantities within 60 days. Use of this device in microenergy circuits leads to total device dissipations in the order of 200 microwatts. Dissipation is so low as to be negligible in its effect on reliability.

Figure 1 shows two micro-energy transistors used in the familiar NOR flip-flop circuit to obtain scaled down current and voltage.

### Micro Memory-Stacks

**Two Serious Limitations of Memory Systems Using Ferrite Cores** have been their large size and their narrow temperature range.

Both of these drawbacks are
Metriseite...is the only device available today that provides a near-perfect combination of **ideal** transducer characteristics. The unusual properties of this remarkable new motion-sensing development are:

- **extreme resolution...** easily measures one ten-millionth of an inch;
- **minute operating force...** absolute minimum bearing friction;
- **negligible reactive force...** a fraction of a milligram;
- **true linearity...** a proven accuracy of $\frac{1}{10}\%$;

New United Funnel Flange design improves reliability of soldered connections

Greater mechanical strength due to greater soldered area of funnel eyelet

WHY UNITED FUNNEL FLANGE EYELETS ARE SUPERIOR

The funnel design permits easy insertion of leads. When soldering, the solder fills the funnels and flows around the outside of the eyelet on both sides of the etched circuit. This increases the soldered areas and seals the lead and the funnel eyelet tightly to the circuit. The unique design of the funnel eyelet permits entrapped gases to escape and makes it possible to achieve an unusually solid, dependable connection.

More uniform circuitry is also realized with United Funnel Flange Eyelets which are made from electrolytic copper. This material has a coefficient of expansion in the same order as that of the copper in the etched circuit.

United Funnel Flange Eyelets meet MIL Standard No. 202 for vibration, shock, thermal cycling, and humidity. Wide choice of sizes and lengths meet needs of hole sizes and board thicknesses. Also available in brass. Special plating and packing to order.

Free: Send us a sample of your board for free insertion of funnel flange eyelets for your testing and evaluation or write for complete specifications of sizes available.

Eliminated by a series of memory devices developed by the Applied Logics Department, General Ceramics Division of Indiana General Corp., Keasbey, New Jersey.

The new memory arrays called MICROSTACKS, are designed for data processing systems that operate under environmental extremes, and their novel construction eliminates the need for temperature-controlled equipment for the entire memory system.

The size of conventional memory stacks is reduced 50 to 1 by a system of arranging the cores on mats, threading the cores with continuous wires, and then folding the planes one upon the other.

As shown in Fig. 1, the mats are arranged side by side and spaced about 1 in. to a in. apart. The X lines are threaded directly through the mats in a horizontal plane. The rest of the Y lines follow the paths shown. The sense and inhibit lines (not shown in the diagram) are then inserted in each mat. Each mat is covered with a suitable insulation that cushions the cores.
against damage or pressure.

The stacks are folded one upon the other, as in Fig. 1B. The folded memory plane is placed in its housing and the leads are brought out to a terminal board or a connector.

Two thermistors are placed in the folded memory, and the unit is covered on all six sides by a heating pad. Encased in its heater pad, the unit is insulated with pads of polyurethane.

Storage capacity of conventional stack (left) is provided by micro-stack unit (center). Complete unit, surrounded by temperature-controlled circuit and insulation is at right.

The memories operate between −55 C and 125 C and a unit consisting of twelve 16 x 16 memory planes occupies but 12.5 cu in.

One design functions at 85 C ± 7 deg in an ambient from −55 C to 85 C. Temperature control is achieved by heating the planes to the maximum ambient and maintaining that temperature throughout the entire ambient range. According to engineers in the division that makes these micro-stacks available, it is simpler, less expensive, and requires less equipment to heat the plane rather than to use air conditioning to do the same job.

The company is working on several other units for other ambients, and for other applications.

The temperature-controlled circuit requires a regulated 3 or 4 v d-c supply at a max of 100 ma and an unregulated 25 v d-c supply at a max of 325 ma.

These micro-stacks were designed to meet all of the necessary military temperature requirements.

**NOW . . . REGULATE 1KV WITH THIS HERMETIC SEAL**

**Miniaturized AC REGULATOR**

NOW . . . nearly a kilowatt of AC power can be regulated by this special Hermetic Seal Unit weighing less than 10 pounds. Built to Mil-E-5400 and Mil-E-5272 specifications, it is primarily magnetic assuring high reliability for critical aircraft and missile power regulation requirements. For regulating three-phase power, a package of three units performs efficiently. Write for literature describing electrical and mechanical characteristics of this entire family of AC Regulators.

**SPECIFICATIONS: MODEL NO. VRAC-104**

**ELECTRICAL CHARACTERISTICS:**

- **INPUT:** 108 to 122 volts
- **FREQUENCY:** 380 to 420 cycles
- **OUTPUT:** 115V ± 1V from 2 to 8 amperes
- **RESPONSE:** <100 ms / 9V in increments
- **DISTORTION:** 5% max over input voltage and frequency range (exclusive of source)
- **OPERATING TEMPERATURE RANGE:** −55°C to +71°C
- **DUTY CYCLE:** Continuous

**ENVIRONMENT CONDITIONS:**

- **Altitude:** to 50,000 ft.
- **Humidity:** 95% 50°C 360 hours
- **Shock:** 15 g's
- **Vibration:** 10 g's 5 to 500 cycles

**MECHANICAL CHARACTERISTICS:**

- **Size:** 5" x 5" x 12"
- **Weight:** Less than 10 lbs.

WRITE FOR BULLETIN NPB-106

HST Special Products Division designs and produces customized regulators, power supplies, servo amplifiers, and other special packaged electronic components for industrial and military uses. Write us your requirements; we will gladly submit recommendations and quotations without obligation.
Fixtures Help Make Bulky Units

Assemblies are frequently employed to maintain dimensional tolerances and reduce the time and cost required to fabricate normal-sized electronic equipment housings. Such fixtures can also be used for bulky assemblies, with comparable advantages.

Twin Coach Co., Buffalo, N.Y., has developed several multipurpose fixtures for electronic equipment shelters and consoles. The type described has foam sandwich walls bonded with epoxy and has tolerances of 0.015 inch in completed dimensions and in wall skin parallelism. Methods may be modified when the sandwiches are poured foam or honeycomb materials.

After detailed parts are formed or purchased, the structural members of each panel are bonded to the skins and the foam. The epoxy the firm most commonly uses for this type of structure is EC 1838 (Minnesota Mining and Mfg.), loaded with aluminum dust to maintain electrical conductivity.

The epoxy is applied on a spreader table equipped with an automatic applicator. The spreader is supported on a gantry which moves the length of the table. Self-feeding adhesive applicators move back and forth and deposit adhesive in front of the comb. Coating thickness is adjusted by micrometer settings. The spreader is reported to spread more evenly than hand-combing and at 7 or 8 times the manual rate. The speed also assures use of the epoxy within its pot life.

Assemblers lay precut foam and structural members in place on the panel skin, using templates as reference layouts. The second skin is placed on top and the panel assembly is moved into a vacuum bonding fixture. The epoxy cures in 12 hours at room temperature while in the bonding fixture.

The bonding fixtures are designed to accommodate a variety of panel sizes and each fixture will hold 4 to 10 panels. The fixtures are loaded with divider plates of 4-inch aluminum between panels. Mylar is installed as a blanket over the top panel and sealed to the fixture top with tape. Vacuum is drawn with a pump. Another pump is held on standby in case the first pump should fail; vacuum is frequently checked by quality control personnel.

As the photo indicates, this fixture's construction is massive. The base plate is 2-inch steel milled on a planing mill to a surface of plus

The three models of Kay DRD Attenuators listed at the right hand side of the table offer the convenience of a direct-reading dial. Attenuation can be varied from 0 db to 119 db in one-db steps by operating two rotary switches. The standard Kay Attenuators operated by six or nine toggle switches are listed at the left. All models are set in lightweight cast bronze housings and offer reduced maximum total error and a negligible insertion loss.
nothing, minus 0.007 inch. The angle steel is gridded on the inside to facilitate evacuation. The fixtures are mounted on support pillars used for heavy aircraft fixtures.

Twin Coach reports that this fixture permits optimum quality control without the expense of individual bonding molds. The fixture cost $3,000 to make; by comparison, a multiple opening press would cost some $50,000, plus supplementary equipment.

Completed consoles

After being bonded, panels are drilled and fitted with attached extrusions and details. The drill fixtures also serve as assembly fixtures, eliminating special coordination of drilled holes in panels and matched parts. The drill plates have holding blocks which locate and hold attachments, so they can also be drilled. The fixture is color-coded for drilling of various panels.

After drilling, the extrusions are fastened and the inserts are potted in place with epoxy. The main assembly fixture is a close-tolerance aircraft type (see photo). The panels are assembled around the fixture, held in position and bonded. At the next stations, subassembly details and hardware are installed and the seams sealed. A Pyle pressure gun is used to apply waterproof sealants. The shelter is then primed.

Air Cools PC Parts
In Hand Soldering

LOW-PRESSURE AIR has been found by Automatic Telephone and Electric Co., Liverpool, England, to be the most efficient method of keeping components cool during the manual soldering of printed circuit boards. A box-shaped fixture is used to hold the board, as shown in cross section in Fig. 1. Connections
NEW NUMBERS
SAME POPULAR TRANSISTORS
SMALL PACKAGE OPTION

THE FAIRCHILD 2N696 and 2N697 are the world's most copied transistors. We have now copied them ourselves in scaled down versions. The 2N717 and 2N718 are exactly the same as these popular types but packaged in the TO-18 case. They occupy 1/3 the volume of the standard TO-5, making them ideal for high-density equipment designs.

With maximum power dissipation of 0.4 watt at a free air temperature of 25°C (or 1.5 watts at a 25°C case temperature), the small packaging still gives more than adequate power handling capability for the majority of applications. All other specifications are identical to those given in the 2N696 and 2N697 data sheets.

These new types are options. Fairchild, as the originator of the 2N696 and 2N697, remains your best source for these most reliable types.

For specification sheets, write Dept. A.
Airpax Choppers for every chopper application

Electromechanical Types
- 50, 60 and 400 CPS standard types
- center-pivoted type for high vibration conditions
- very low noise models where chopper noise must be less than 4 microvolts
- high temperature series
- double-pole double-throw choppers for signal mixing
- transistor drive types
- coaxial choppers for VHF
- additional types for special applications

Transistor Types
- subminiature types for limited space requirements
- high voltage series for high signal levels
- high temperature choppers for 125°C operation
- miniature molded units for printed circuit use
- SPST or SPDT types

Whether your application is for Servo Systems, Computers, Telemetering and Multiplexing Equipment, Amplifier Stabilization or Modulation-Demodulation, Airpax produces a chopper specifically designed for the purpose. The types listed are basic. Most types are available in a variety of mounting and header styles.

Airpax Electronics Incorporated
Cambridge Division, Cambridge, Maryland

Airpax choppers are soldered with a 25-watt miniature iron. Two methods are used by the company to replace printed circuit board components. In the factory, the component leads are cut close to the component body. The leads are straightened, solder heated and the leads removed. In the field, leads are also clipped and straightened, but not removed. Leads of the new part are wrapped 1/2 turns around the old leads and soldered (Fig. 2).

Vibratory Finisher Uses Air Suspension

Air suspension helps regulate vibratory amplitude of vibratory finishing equipment made by Pangborn Corp., Hagerstown, Md. Four rubber air cushions are mounted above the vibrating platform and four are mounted below. Each series is pneumatically interconnected, allowing amplitude to be varied by varying the air pressure. Amplitude is also changed by adjustable weights on the motor-driven eccentric shaft. Vibratory finishing is used for the same purposes as tumbling or barrel finishing. It can be used to finish both large and fragile parts without damage since there is no sliding or rolling action. The parts being finished are suspended in the media.
do you know what's expected from semi-conductor materials?

There were more than a dozen articles on semi-conductor materials in electronics in recent months. Each was specially edited to give you all key facts, ideas or trends—and there's more coming! Accurate electronics' reporting tells you what's happening now... what's expected in materials and components. Don't miss dozens of articles on basic subjects edited to keep you informed, help make your research, development, sales and marketing plans pay off. It pays to subscribe to electronics (or renew). Fill in box on Reader Service Card now. Easy to use. Postage free.

FIND WHAT YOU NEED IN electronics

Whether an interval is a month or a microsecond, you can measure it, divide it, record it, or use it for control with an A. W. Haydon Company custom-designed or standard timer. Every type, every size, every class... timing motors, time delay relays, interval timers, repeat cycle timers... you name it, we make it. If you ever have a specific timing problem, the least you can do for yourself is get our literature. In fact, why not send for our Bulletin on the 14100 Series DC Motor (above) right now. This two-ounce sub-miniature DC Timing Motor is less than 1" in diameter, 1½" long. Used to drive a miniature tape recorder in the Vanguard II weather satellite (expected to remain in orbit for 200 years), it represents the high capability of The A. W. Haydon Company in timing devices.
Solar Concentrators

WEIGH 0.3 LB PER SQUARE FT

Solar concentrators weighing less than 0.3 lb per square foot, with concentration efficiencies approaching 90 percent, have been developed by the Energy Research Division of Electro-Optical Systems, Inc., 170 N. Daisy Ave., Pasadena, Calif.

The concentrator is designed to meet the needs of auxiliary power systems for space.

Shape of the concentrators is either a paraboloid of revolution or a Fresnel mirror. Structure of the concentrators is either rigid-deployable or nonrigid. Nonrigid types are either folding or inflatable, while the rigid-deployable is primarily a folding unit.

Aluminum, beryllium, and nickel are among the metals being used in making the concentrators. Plastics such as Mylar are also being used.

Transistorized Tv Tuners

HAVE LOW NOISE FIGURE

Construction of transistorized television tuners with high gain and low noise figure has resulted from a joint development effort of the Lansdale Division, Philco Corp., Lansdale, Pa., and the F. W. Sickles Division of General Instrument Corp. A standard Sickles mark 6 tuner was modified.

The tuners use new low-noise MACT germanium transistors. The units are scaled-down versions of Philco MACT transistors presently being mass produced. Availability of the new units is expected in the near future. The new transistors have noise figures less than 3.5 db at 200 Mc with the best units as low as 2.6 db.

The transistorized tuner has a noise figure that varies from a maximum of 4.6 db on high tv channels to 3.3 db on low channels. Power gain varies from 32 db on the high channels to 45 db on low channels.

Ga Arsenide Transistor

WITHSTANDS 250 DEG C

A gallium-arsenide transistor capable of withstanding the extremely high temperatures encountered in jet aircraft, missiles and space vehicles has recently been announced by Radio Corp. of Amer-
In November of 1957, the first Ultra Long Life NIXIE Indicator Tube was developed and put on life test. In 1958, the first 100 production tubes joined this life test which subjected the tubes to the most severe conditions, i.e., constant “lighting” of one of its 10 numbers. To date, not one life failure has been experienced. This rigid test has been in progress in excess of 10,000 hours which is the equivalent of more than 50,000 hours of normal usage.

In applications from milling machines to computers to digital voltmeters, to counters, tens of thousands of Ultra Long Life Nixie Indicator Tubes have been operating over one year without a single life replacement.

ANOTHER ELECTRONIC CONTRIBUTION BY Burroughs Corporation

ELECTRONIC TUBE DIVISION
Plainfield, New Jersey

CIRCLE 109 ON READER SERVICE CARD
ica, 30 Rockefeller Plaza, New York.
The transistor is a developmental
diffused-junction drift-field type.
The gallium-arsenide transistor
works at temperatures exceeding
250 degrees C as compared with
175 degrees C for silicon trans-
istors.
The transistor has an alpha cut-
off frequency of approximately 100
Mc. The voltage capabilities of the
junction compare favorably with
those of silicon transistors. The
transistor operates at current levels
up to 80 ma and its general behavior
is similar to a silicon unit.

CIRCLE 304 ON READER SERVICE CARD

Broad-Band Pulse Receivers
COVER 45 TO 10,750 MC BAND

INTERCEPTION and analysis of pulsed
signals in both airborne and ground
installations is the job of a new se-
ries of wide open broad band pulse
receivers announced by Granger As-
soociates, 974 Commercial St., Palo
Alto, Calif. Three of these new re-
ceivers cover the entire 45 to 10,750
Mc spectrum with sensitivities ap-
proaching those of superheterodyne
equipment.

All of these receivers employ r-f
preamplifiers with specially de-
signed crystal-video circuits. In the
frequency range between 45 Mc and
550 Mc, stagger tuned preamplifi-
ers are used. Above 550 Mc, perma-
nent magnet-focused traveling wave
tubes are used. Video amplifiers
are completely transistorized, as are
their power supplies. Output of each
channel is separately available for
video analysis, and—in stretched
form—for recording. Provisions for
blanking are also included.

The receivers are available in
either relay rack or standard airc-
raft ATR packaging. Power re-
quirements are 109 to 121 v a-c; 50
to 800 cps for rack mounted ver-
sions and 360 to 800 cps for air-
borne versions. ATR cases are pro-
vided with stock trays. Rack
mounted packaging is for standard
19-in. relay racks.

CIRCLE 305 ON READER SERVICE CARD

Peak Following Amplifier

PROVIDES UP TO 100 MA

A PROPORTIONAL d-c level for each
peak of acceleration is produced by
the model V63 peak following am-
plifier developed by Video Instru-
maments Company, Inc., 3002 Pennyl-
vania Ave., Santa Monica, Calif. The
device is used to amplify sig-
nals from crystal type accelerometers.
The device makes it possible to
use peaks of sine waves or ran-
dom waves as control functions.
In vibration tests, safe limits can be
established by a reference volt-
age. Whenever the d-c output level
of the amplifier exceeds the refer-
ence voltage, a relay is energized
and can be used to shut down the
test, or sound an alarm, before the
test becomes destructive.

The amplifier provides up to 100
Ma. This output makes it possible
to drive high-frequency recorders.
If the chart speed is sufficiently
slow, the resulting curve will be the
envelope of the vibration curve. Thus
the amplifier can be used for
data reduction.

The input impedance is over 1,000
megohms. Bandwidth is from 5 cps
to 5 kc. The output is d-c coupled,
at an impedance of less than 1 ohm,
from d-c to 5 kc. The unit has an
integral, regulated power supply.

Submersion Actuators

WORK UNDER SALT WATER

AUTOMATIC SAFETY release is pro-
vided by an actuator that when sub-
merged in salt water, closes an elec-
trical circuit to release compressed
gas for inflating aircraft life rafts,
escape capsule flotation bags and
floation bags for missile nose
cones. The product was developed
by Kidde Aero-Space Division,
Walter Kidde & Co., Belleville, N. J.
Salt water acts as an electrolyte
in the actuator. It completes a cir-
cuit thus firing a cartridge or ex-
plosive squib to open a passage in a
valve on the compressed gas con-
SOLA AC and DC voltage regulation

Continuous, automatic, maintenance-free

Sola Constant Voltage Transformers and Regulated DC Power Supplies provide dependable, regulated output voltage. Their output regulation is unaffected by wide variations in input voltage.

Sola CV Transformers are static-magnetic regulators with completely automatic, continuous regulating action. Their response to variations in input voltage is usually 1.5 cycles or less. They have no moving or renewable parts and require no maintenance.

Each Sola Regulated DC Power Supply incorporates a constant voltage transformer in combination with a semiconductor rectifier and a high-capacitance filter section. This combination makes the power supply compact, dependable, and efficient; and assures sustained output voltage in the face of pulse or intermittent loads, or heavy, short-time overloads.

Sola Constant Voltage Transformers

Standard Sinusoidal Type provides voltage regulation of ±1% with primary voltage variations as great as ±15%. With less than 3% total rms harmonic content in their output voltage wave, these units are desirable for use with equipment having elements sensitive to power frequencies harmonically related to the fundamental. Available in nine ratings, 60va to 7.5kva.

Normal-Harmonic Type also provides ±1% regulation at somewhat less cost. This group has an average of 14% total rms harmonic content in its output voltages and is suited to equipment not extremely sensitive to voltage wave shape. The series includes those mechanical designs specially engineered for use as built-in components. Nineteen stock ratings range from 150va to 10kva.

Adjustable Sinusoidal Type provides ±1% regulated output—output adjustable from 0-130 volts and one fixed at 115 volts. Has less than 3% total rms harmonic content in output voltage. Portable for use in shop or laboratory, or mount on standard relay rack.

Electronic Power Type regulators provide ±1% regulated filament voltage at 6.0 and 6.3-volt levels; or a combination of plate and filament voltages regulated ±3% for ±15% input variations. Filament regulators are available in ratings from 2.3 to 23 amps. One model is specially designed for portable lab or shop bench use; it has a 30va rating. Combina-
tion plate/filament regulators, in three stock sizes, are designed to operate with commonly-used rectifier tubes.

Custom-designed units can be supplied in production quantities in ratings from 10a to 25kva to suit individual specifications. Custom designs can include special mechanical structures, various voltage ratios, special frequencies, compensation for frequency variations, multiple output voltages, three-phase service. Units can be manufactured to military specifications.

For additional information on Sola Constant Voltage Transformers, write for Circular 78-CV

Sola Constant Voltage DC Power Supplies

For intermittent...variable...pulse...or high-current loads

Fixed-output-voltage designs are available in six stock models with ratings from 24v @ 6a to 250v @ 1a. They are extremely compact, light-weight, and moderately priced in proportion to their power output and performance.

Adjustable-output designs provide a considerable range of regulated dc voltages. Accessory handles offer portability and permit self-stacking. Six models are available with outputs ranging from 5v @ 7a to 400v @ 0.6a.

For additional information on Sola DC Power Supplies, write for Circular 75-DC

CONTROLLER SOLID STATE TIMING MODULES

Originally developed and produced for use in Tempo's service-proven Time Delay Relays and other timing systems, these modules are now available as individual "building block" units. Their sub-miniature size and weight, plus excellent resistance to severe environmental conditions, make them particularly suitable for missiles, spacecraft and other critical applications.

CONTROL VERSATILITY

The basic module provides a precise time delay between application of input voltage and turn-on. A unique 'set-reset' control line is included to allow instantaneous turn-on or turn-off at any time without interrupting the input voltage. By employing the control line function, together with the application of various standard logic blocks, a wide variety of precision timing devices and controls can be constructed by the user. Typical of these are Logic Function Time Delay Circuits, Electronic Step Relays, Multi-Channel Pulse Programmers, Repeat Cycle Timers, Pulse Train Generators.

FIXED OR ADJUSTABLE TIMING

Both fixed and adjustable time modules are available. In fixed types, delay periods may be specified from .00005 seconds to 300 seconds. In the adjustable types, the minimum adjustment range is from .00005 to .300 seconds—the maximum is from 15.0 to 300 seconds. Fifteen intermediate ranges are also available, each with a 20 to 1 spread. Adjustment is made by a simple, quick change of an external resistance value—no special calibration equipment or elaborate procedures are required.

GUARANTEED ACCURACY

Accuracy ratings of 10%, 5%, or 3% are available in fixed types; 10% or 5% in adjustable types. These timing accuracies are guaranteed under any combination of operating and environmental conditions including:

- Input Voltage: 18 to 31 vdc
- Temperature: 35°F to +125°F
- Vibration: 20 g's, 2000 cps
- Shock: 50 g's, 1 millisecond
- Acceleration: 20 g's, steady state
- Maximum load current rating is 100 millamps resistive. Units are available to switch the load to ground or switch power to the load. A typical module, housed in a 1-inch cube case, weighs only a fraction more than 1 ounce. Special-order types are available for other requirements of delay times, accuracy and load ratings, switching action, etc.

Write For Engineering Bulletin 5906

Complete technical description and specifications plus detailed how-to information on circuit and system applications.

These highly engineered modules are manufactured in compliance with Tempo's exacting Quality Assurance Program, including functional testing of each unit under all combinations of rated temperature and voltage extremes.

It is quite probable that most people today think of and define Time in considerably more finite terms than did Spinoza, and they would immediately express their disagreement with that eminent philosopher. Yet a philosophy as all-encompassing as Spinoza's should not, because of its seemingly unreal, intangible nature, be hastily dismissed. Instead, it should serve to stimulate no small measure of lively thought and discussion.

Tempo Instrument Incorporated, Hicksville, L. I., New York
with microfilming... it's the DETAILS that count!

And with a DEA-GRAPH camera from BRUNING, you get 120 lines per millimeter resolution at a 30 X reduction!

It's all there... when you enlarge a Dea-Graph reduction from your files, the finest pencil detail in any drawing or plan is clearly reproduced.

When you get into microfilming with a Dea-Graph camera, you've taken the right first step to permanence. Dea-Graph offers you delicate precision, timed and operated so automatically that you don't need to be a camera expert to get first-quality results.

The price makes it hard to believe, but Dea-Graph gives you these extra features without increased cost: six lamp illumination that brings out and balances every detail of each drawing or plan... automatic focusing so even a non-expert can get impressive results... film magazines that can be removed with safety in the convenience of a lighted room... double track camera column for rigidity... and the Dea-Graph planetary microfilm camera can be converted easily into an enlarger unit.

If you're interested in getting a microfilming program underway at your place, we'll be glad to help you approach it with a sound, practical plan. Mail in this coupon today and you'll have the benefit of a specialist... the Bruning Man...to help you consider microfilming in terms of your own needs and your own budget.

Electronic Timer TRANSISTORIZED

The Sloan Co., 7704 San Fernando Road, Sun Valley, Calif., has in production a transistorized electronic timer capable of handling 25 amperes, 32 v inductive over an ambient temperature range of -55°C to +125°C. Designed primarily for applications where multiple pulsing can be used to trigger a number of programmed functions, model 308 timers are basically high current capacity, free-running pulse generators with externally adjustable period and pulse.

Delta Unit CAPACITIVE TYPE

The Decker Corp., 45 Monument Road, Bala-Cynwyd, Pa. The 904-1 delta unit is a capacitive type general purpose displacement measuring system utilizing the T-42 ionization transducer. It permits non-contact static and dynamic measurements in the milli- to micro-inch region with an output of ±30
We promise you a reply by telephone or wire within 48 hours after receipt of your inquiry!

new openings in space age electronic projects

Hughes Engineering Division offers experienced graduate engineers and physicists a choice from nearly 100 openings on Hughes projects which include:

- Digital Computer for Polaris Guidance
- Infrared Applications for ICBM Surveillance
- Space Ferry
- Satellite Communications
- Pulsed Doppler Radar for Anti-Submarine Warfare
- Advanced Air-To-Air Missiles
- Automatic Check-Out Equipment
- Space Radiation Measurement and Detection

Training and experience should be applicable to the research, development, design and testing of advanced electronic equipment for use in space vehicles and supersonic military aircraft; in solid state physics, nuclear electronics, industrial dynamics, and related areas.

Use of the following form will, we hope, reduce to a minimum the inconvenience of submitting an employment inquiry, yet will still permit us to give you a reasonably definitive reply.

Please airmail resume to:

the tough jobs 
go to Frenchtown

Ask any engineer why he selects Frenchtown first for those "must" jobs, and chances are he'll sum up his answer in a single word—confidence!

It's the reason, too, why more and more engineers make Frenchtown their number one supply source for high temperature ceramics, components, assemblies, ceramics-to-metal seals, metallized ceramics, and specialized body compositions.

Next time you are faced with one of those "tough jobs" and want to be sure to come up with the right answer—fast, check with Frenchtown. You'll be in good company.

Literature is available on Frenchtown materials and products. We'll be happy to send you copies without obligation. Write today.

Vane Axial Blower
FOR HIGH OUTPUT

GLOBE INDUSTRIES, INC., 1784 Stanley Ave., Dayton 4, Ohio. Type GR vane axial blower operates on 115 v a-c, 60 cps, and delivers 220 cfm of air at 1.75 in. H.O static pressure, and 315 cfm at 0 in. back pressure. Maximum current at free air delivery is 1.8 ampere; speed is 8,000 rpm. Unit is designed to meet MIL specs. Blower measures 47 in. in diameter and is 61 in. long; weight is approximately 4.5 lb. Mounting is made with 6 bolts to the front flange. Unit can also be operated on d-c power since a universal motor is employed.

NEW STRIPPIT FLEX-O-DRILL

Are you looking for a way to reduce layout and template making time? Other manufacturers of sheet metal products and printed circuits have cut that time in half with the Strippit Flex-O-Drill.

This table-type, extremely accurate machine drills, reams, center punches and scribes without base line drawings or vernier height gauges. Positioning of the bridge and drill carriage is done with adjustable steel tapes calibrated to 0.100". Micrometric gauges then bring the setting to the nearest 0.001". Lead screws are precision ground and engaged only during micrometric gauge settings, thus speeding adjustment and minimizing wear. Capacity is ¼" mild steel—up to 24" width—any length.

Anybody who can read blueprints and knows something about layout practice can learn to work the Strippit Flex-O-Drill in a few minutes. We'll be happy to prove this with an actual demonstration at your own plant. Write for information today.

WALES STRIPPIT INC.

IN TOUCH WITH NEW DIMENSIONS

Another achievement of IBM Applied Scientists: general computer program for job shop simulation

Creating imaginative solutions to problems never solved before is a job of IBM Applied Science Representatives. Through unique applications of data processing, they are exploring new dimensions in engineering, the sciences, and business.

One team of Applied Scientists, for example, worked closely with customers to simulate industrial job shop operations on a computer. A general program for this purpose allows firms to pre-test changes in production scheduling.

Other Applied Science Representatives are working on design analysis, forecasting, problems of mathematical computation, and process control. The range of projects is unlimited.

You may play an important and rewarding part in this stimulating profession. There are openings in many cities for men and women with advanced degrees in engineering, mathematics, or a physical science, or a degree in one of these areas plus a Master's in business administration or experience in programming.

For a confidential interview, please call any IBM Branch Office or one of these Regional Managers of Applied Science:

DATA PROCESSING DIVISION IBM®
now...analyze both SSB & AM transmitters & receivers faster, over a wider frequency range (100 cps-40 mc) at minimum cost

Panoramic adds important NEW design features to the time-proven Model 5563! Now, in one convenient, compact package, you get the comprehensive unit you need to set up, adjust, monitor and trouble shoot SSB and AM transmitters and receivers.

**TWO TONE TEST**
Fixed sweep width 2000 cps. Full scale log sideband tones 1.5 kc and 2.1 kc from carrier (not shown). Odd order I. M. distortion products down 37 db.

**HUM TEST**
Indication of one sideband in above photo increased 20 db. Sweep width set to 150 cps reveals hum sidebands down 53 db and 60 db.

*See Panoramic Analyzer No. 3 describing testing techniques, etc., for single sidebands. A copy is yours for the asking.

**GREATER FREQUENCY RANGE**
100 cps-40 mc, with optional NEW MODEL REC-1 Range Extending Converter. . . speeds distortion analysis of receiver AF and IF outputs, and transmitter bass band.

**NEW 2-TONE AF GENERATOR MODEL TTO-2**
2 generator frequencies, each selectable from 100 cps-10 kc • Resetable to 3 significant digits • Accuracy: ± 1% • Output Levels: each adjustable from 2 to 4 volts into matched 600 ohm load • Output DB Meter • Spurious, hum, etc., less than --60 db • 100 db precision attenuation in 1 db steps.

**FASTER-NEW, built-in motorized tuning frequency control (in addition to manual tuning)**

**ALL THESE NEW FEATURES . . . PLUS**
**A SENSITIVE SPECTRUM ANALYZER**
Panoramic's Model 5B-12a5 Panalyzer. Pre-set sweep widths of 150, 500, 2000, 10,000 and 30,000 cps with automatic optimum resolution for fast, easy operation. Continuously variable sweep width up to 100 kc for additional flexibility. 60 db dynamic range. 60 cps hum sidebands measureable to --60 db. High order sweep stability thru AFC network. Precisely calibrated lin & log amplitude scales. Standard 5" CRT with camera mount bezel. Two auxiliary outputs for chart recorder or large screen CRT.

**INTERNAL CALIBRATING CIRCUITRY**
Two RF signal sources simulate two-tone test and check internal distortion and hum of analyzer. Center frequency marker with external AM provisions for sweep width calibrations.

**Reset Timer MULTIUNIT**
ZENITH ELECTRIC Co., 152 W. Walton St., Chicago 10, Ill. A new multiunit reset timer panel provides automatic control of eight sequential operations. Known as model 8AZC, each timer is calibrated from 0 to 60 sec. Timing ranges up to 10 minutes can be supplied. Unit illustrated controls operations in a plastic vacuum molding machine. Each set of timers controls a complete operation which consists of draping the plastic sheet over the mold, heating and drawing it down with a vacuum action. It is operated by a limit switch and is fully automatic.

**Color Coded Cables PLASTIC JACKETED**
LENZ ELECTRIC MFG. Co., 1751 No. Western Ave., Chicago 47, Ill. To promote the rapid and easy identification of cables, the company is introducing plastic jackets in the standard color shades adopted by the industry. Color coded in this way, the cables connecting the units of electronic equipment can be...
quickly identified as to function and circuit, before, during and after installation. The cables in color plastic jackets are available with any size and number of conductors.

**Transfer Switch**

**K AND X BANDS**

**TRANSCO PRODUCTS,** 12210 Nebraska Ave., Los Angeles 25, Calif., has in production a newly designed K-band transfer switch. Also available for X-band, the switch can be operated as spdt or double pole transfer. Both size and weight are said to be minimum presently available for waveguide transfer switches. Typical specifications of this 28 v d-c motor actuated switch are: vswr 1.05; insertion loss 0.07; crosstalk 80 db.

**Frequency Counter**

**IN-LINE DISPLAY**

**BERKELEY DIVISION**, Beckman Instruments, Inc., 2200 Wright Ave., Richmond, Calif. New frequency counters feature an in-line display with all digits formed on the surface plane. This display is not only readable from the front but from the top or from the side at angles as close as 30 deg to the face. The digits, 1½ in. high, are colored bright red so that the display will be clearly visible in high ambient light.

**PW-200 Packaged Pumping System**

**IT'S MOBILE... CAN BE MOVED ANYWHERE!**

- EASY TO CONVERT TO A VACUUM EVAPORATOR
- PRESSURES TO $5 \times 10^{-7}$ MM HG
- STURDY, VERSATILE, DEPENDABLE

The popularity of KINNEY Packaged Pumping Systems stems from the fact that they are so downright useful. They'll evacuate chambers, tanks, bell jars, furnaces, tubes or equipment anywhere and quickly. With main valve closed, the KINNEY PW-200 will attain ultimate pressures to $5 \times 10^{-7}$ mm Hg with no coolant in the trap ($5 \times 10^{-7}$ mm Hg with coolant).

The Rotatable "T" Manifold is a feature of KINNEY Packaged Pumping Systems. The stem of the "T" can be rotated a full $90^\circ$—from horizontal or vertical—so that the system is readily converted to form a complete Evaporator by the addition of a suitable baseplate. Get the facts on the PW-200 and other KINNEY Packaged Pumping Systems.
...Where only a Precision Wirewound is Precise Enough!

Shallcross

"P" type RESISTORS

As specialists in precision wirewound resistors and resistor assemblies for over 30 years, Shallcross offers unmatched experience in meeting the most exacting matched resistor requirements. Encapsulated "P" Types illustrated are available in over 25 basic types—many to critical MIL-R-93A, MIL-R-93B, and MIL-R-9444 Specifications. Detailed performance comparisons to applicable MIL specs are available for all types.

SHALLCROSS MANUFACTURING CO., 2 Preston St., Selma, N. C.

D-C Amplifier DIFFERENTIAL TYPE

REDCOR DEVELOPMENT CORP., 14750 Armita St., Van Nuys, Calif.

Model 361 differential amplifier has a new input circuit that provides: common mode rejection of 120 db minimum, d-c to 150 cps, at amplifier gain of 1,000; allowable line unbalance 1,000 ohms either line; amplifier bandwidth d-c to 200 Kc minimum; input impedance from either input terminal 1,000 megohms minimum. These features allow wide-band amplification with common mode rejection equal to that of narrow-band amplifiers.

Amplifier-Converter TRANSISTORIZED

THE MIRA CORP., 2656 No. Pasa- dena Ave., Los Angeles 31, Calif., has a new miniature data-amplifier converter with high input impedance for use in airborne instrumentation applications requiring the amplification and conversion of millivolt level a-c data signals. Unit converts a modulated carrier input to a d-c output, the polarity of which is determined by the phase of the input signal relative to an a-c reference voltage. Silicon transistors provide the unit with a gain
IT'S WHAT'S IN HERE THAT COUNTS

MASSA Announces 40 MM AMPLITUDE with RECTILINEAR INK RECORDINGS

Portable two channel Meterite Model BSA-250
- 40 mm amplitude
- Frequency Response, DC to 120 cps
- Rectilinear recordings on economical ink chart paper (save more than $3000 in 200 operating hours over other rectilinear charts, running at an average chart speed of 50 mm/sec.)
- Choice of interchangeable plug-in preamplifiers
- Transistorized driver amplifiers with individual power supplies
- 6 Chart speeds .5 to 200 mm/sec.
- Event marker with internal push button control.

MORE DATA PER DOLLAR

Eight channel recording system, Model BSA-850
- 40 mm amplitude
- Frequency response DC to 120 cps
- Rectilinear recordings on economical ink chart paper (save more than $6000 in 200 operating hours over other rectilinear charts, running at an average chart speed of 50 mm/sec.)
- Choice of interchangeable plug-in preamplifiers
- Transistorized driver amplifiers with individual power supplies
- 18 speeds push button controls .5 cm/hr to 200 mm/sec.

* PREAMPLIFIERS — All Massa Recording Systems are designed to accept a wide choice of plug-in Preamplifiers to satisfy every recording requirement.

Trimming Pots
ALL-METAL UNITS

ANALOGUE CONTROLS, INC., 200 Frank Rd., Hicksville, N. Y., has available a full line of square trimming potentiometers. Overall dimensions are \( \frac{1}{2} \) by \( \frac{1}{2} \) by \( \frac{1}{4} \) and \( \frac{1}{2} \) by \( \frac{1}{2} \) by \( \frac{1}{4} \). The rugged all-metal units operate to 150 C. They are designed to meet or exceed MIL-ES272B and NAS710, and are available in all resistance ranges. A spring-loaded worm gear assures reliable zero backlash positioning with wiper position completely insensitive to shock and vibration. The wiper is of the non-bridging type, and therefore does not short the potentiometer terminations.

Tunnel Diodes
FIVE TYPES

SPERRY SEMICONDUCTOR DIVISION, Sperry Rand Corp., South Norwalk, Conn., announces types T101-T105 germanium tunnel diodes with peak currents ranging from 0.8 ma to 20.0 ma. Peak to valley current ratios on all types are in excess of 5.0 to 1, typically 8.0 to 1. Offering many inherent design advantages, including small size, reliability, radiation-resistance, wide temperature range and high cutoff fre-
Tape Wound Cores

Bobbin Cores

Not only G-L but our customers, too, claim consistent uniformity with every G-L Tape Wound Core and Bobbin Core. This consistent uniformity is the result of: an accuracy of control never before achieved in each and every step of the manufacturing process; the use of the highest quality raw materials and new and exclusive manufacturing technologies.

Prove our claims and the claims of our customers, Write, wire, call or teletype us about your requirements and for our technical bulletins.

alpha has systems management capabilities in many fields

Telecommunication systems... such as SAC's "Short Order"... are just one of Alpha's areas of capability

Do You Have Diverse Systems Engineering Capabilities?

Alpha functions at the systems level, depending upon reputable and competent manufacturers for the original design of subsystems. Alpha personnel devote their time and energies to the dynamic, economic, and logistic interaction of the individual entities which make up the system. Concentration upon the system as an entity enables Alpha to answer the need for centralized management control of complete systems.

- Alpha current prime contracts include:
- HF SSB communications systems for the Strategic Air Command
- Integrated Fleet Communications System for the U. S. Navy
- Ground based deep space and satellite surveillance systems for the Signal Corps (ARPA) and the Jet Propulsion Laboratory (NASA)
- Telecommunications and command-destruct systems for major missile ranges
- Ground and air transportable electronics systems, including high power communications
- Tropospheric scatter communication system in the Far East for the U. S. Army
- Scatter/microwave communications systems for commercial companies

Alpha assumes responsibility not only for the electronic equipment, but also for the outside plant and other equipment and structures necessary to an operative system. Do you have capabilities in the design, engineering and implementation of complete systems? Write:

NEW BOOKS

Advances in Semiconductor Science

By HARVEY BROOKS.

This volume is a compilation of the 137 papers presented at the Third International Conference on Semiconductors held at the University of Rochester, New York, 18-22 August 1959. Ordinarily one does not find the proceedings of a scientific meeting to be worthy of publication in book form, there generally being a prevailing lack of continuity and cohesiveness in the content of the average technical meeting. Such is not the case here; the present volume is an excellent chronicle of an outstanding scientific conference and should be a must for the library of all physicists and engineers engaged in advanced semiconductor research.

The book is divided into 20 sections corresponding to the various sessions of the conference. The topics range from basic solid state theory through recombination and transport phenomena to optical, magneto-optical, thermo- and galvano-magnetic effects. Except for the survey papers dealing with the broader aspects of the semiconductor field, many of the articles represent rather significant new work by already well established research workers. The subject matter is sufficiently diverse and the specific areas self-consistent so that the reader gains a fairly good insight into the latest developments and their effect on the general store of knowledge in a particular field. In many cases this is augmented by virtue of the compilation of "from the floor" discussions at the end of each session.

Continuity is afforded through the truly excellent survey articles by the outstanding international authorities who cover the entire semiconductor field in their treatises. It is in this particular aspect that your reviewer finds this volume to be of great value.

The three papers of the opening session set the stage and present the theme of the conference as an entity. The status of semiconductor

This two-volume set stresses principles rather than specific pro-
dure, thus organization and content differ from the traditional
physics text for engineers and scientists. Part I deals with
mechanics, wave motion and heat; Part II with
electromagnetism, optics and quan-
tum physics.

Many topics are treated in
greater depth than customary and contemporary material is woven into the basic framework. Omitted entirely or treated only indirectly are simple machines, surface tension, viscosity, calorimetry, change of state, humidity, pumps, practical engines, musical scales, architectural acoustics, electrochemistry, thermoelectricity, motors, a-c circuits, electronics, lens aberrations, color, photometry and the like.

General nature of key ideas common to all areas of physics—such as conservation laws of energy, linear and angular momentum, and charge—are emphasized. Approach to quantum physics is not the traditional one, rather contemporary concepts are developed fairly rigorously.

Mathematically, the authors assume the reader is at least taking a concurrent course in calculus. A number of thought provoking problems are given; none require extension of text material, contemporary applications or derivations, few can be answered directly from text or by plugging values into equations. Examples are presented with algebraic instead of numeric solutions.

Supplementary material of an advanced, historical or philosophical character is printed in small type. This feature plus the optional nature of some chapters permit use in physics courses of various lengths.

The mks instead of cgs system of units is used throughout. Illustrations are clear and readable, even a Pogo cartoon is included.

Although some college graduates will be shocked at the scanty treatment given their favorite topics, the reversion to basics is indeed welcomed by this reviewer.—WEB

THUMBNAK REVIEWS

Servo Engineer's Handbook. Daystrom Transicoil, Division of Daystrom, Inc., Worcester, Pennsylvania, 128 p, $8.00. This approach to servos is by no means a complete handbook and to that extent the title is misleading. Principle elements of a servo are discussed in eight separate chapters. The emphasis is practical rather than theoretical, but there is some mathematical development.

Health Physics Instrument. By J. S. Handloser, Pergamon Press, New York, 182 p, $6.50. This first volume in the health physics division of an international series of monographs...

Full information is available for the asking!
you'll need help!

If you earnestly feel the only way to get the kind of pots you need is to build 'em yourself — a word of caution. Don't start off alone — gather a few choice friends around to assist with the problems you might run into. There's the little matter of metals engineering, plastics, contact engineering, chemical, metallurgy and other assorted engineering areas. Otherwise, you might never get through all these little details!

But don't waste time putting your friends through engineering school — Ace has a staff of specialists and consultants all recruited for just such design problems! They save us — and in turn — our customers, needless concern over the stumbling blocks which may arise. So if a unique design solution to your pot requirements is what you're after, don't hesitate! See your ACErep!

Here's a typical bit of ACE collaboration: Our A.I.A. 1-1/16" size ACEPOT®, servo-mount.

covering entire field of nuclear energy contains descriptions, characteristics and uses of common types of radiation detectors. Content has been primarily designed for those beginning to use radiation and who wish information concerning basic health physics instrumentation procedures. Although the field is still open and new developments will come thick and fast, this book adequately fulfills the needs of the immediate and near future.

Principles of Frequency Modulation. By B. S. Camies, John F. Rider Publisher, Inc., New York, 147 p., $3.50. Written specifically for students, radio engineers and amateurs, this book discusses basic theory of f-m, interference, generation and detection of f-m waves, f-m receivers, and nonbroadcasting applications of f-m. Although treatment is adequate, the price seems too high for a comparatively brief, paper-back edition.

Advanced Engineering Mathematics. By C. R. Wylie, Jr., McGraw-Hill Book Co., New York, 1960, 696 p., $9.00. This completely rewritten second edition of the original 1951 book still sticks to the original objective — to provide an introduction to those branches of advanced mathematics currently important to engineers and physicists. Two new chapters on determinants and matrices, and finite differences are included. The long appendix and glossary devoted to a review of calculus have been omitted as is the chapter on fluid mechanics. Users with a good background in calculus will have no trouble following the text.

Electronic Computers—Principles and Applications. By T. E. Ivall, Philosophical Library, New York, 1960, 263 p., $15.00. This almost completely rewritten second edition now includes chapters on analog computer circuits, programming of digital computers and evolution of more intelligent machines. The book serves as a nonmathematical introduction to computers and has been written for technicians, engineers and students with some knowledge of electrical or electronics engineering. Although text is primarily devoted to describing circuits and construction, considerable emphasis is given to application of automation or control techniques in industry. Considering the technical level and brevity, the price seems out of line.

How to Get the Most Out of Your VOM. By Tom Jaski, Gernsback Library, Inc., New York, 1960, 224 p., $2.95. A technician's handbook, paperbound, slanted to take the mystery out of servicing with commercially-brought or kit-wired volt-ohm-milliammeters. Well organized and illustrated, with playdown on trade marks. Text emphasis is on solving practical problems generally encountered in lab or field.
Specialized aircraft motors developed by AiResearch operate at temperatures from −425° to +600°F ambient. The range of this compact, lightweight, ½ H.P. motor is −65° to +600°F.

AiResearch diversification and experience provide full capability in the development and production of electromechanical equipment and avionic controls for aircraft, ground handling, ordnance and missile systems.

A.C. and D.C. Motors, Generators and Controls • Inverters • Alternators • Linear and Rotary Actuators • Power Servos • Hoists • Electrical Pyrotechnics • Antenna Positioners • Positioning Controls • Temperature Controls • Sensors • Williamsgrig Connectors • Static Converters.

H-P: the personal touch

A supervisory development program under way at Hewlett-Packard is expected to provide the key to more "personal" personnel relations despite rigid expansion.

The fast-growing Palo Alto, Calif., electronics firm has seen its employee roster increase from fewer than 1,500 in 1957 to more than 2,400 today in the parent corporation alone. There are an additional 700 in outlying, recently-acquired subsidiaries and divisions.

This phenomenal growth, while a source of great satisfaction to top management of the company, has also provided a certain amount of apprehension. As late as 1957 Bill Hewlett and Dave Packard, founders, and Noel Porter, vice president and head of production, had personally handled the major part of personnel matters in the organization. They came to realize, however, that as the company grew larger they could not physically handle this type of task.

In 1957 Ray Wilbur was hired as personnel manager. His initial job, beyond setting up a personnel staff and system, was to pull together and coordinate the various training programs that had been initiated independently by different department supervisors.

The concept of a comprehensive supervisory program developed from the initial work with these training programs. In March, 1959, Wilbur hired Lee Seligson to organize and administer such a program.

The problem at H-P could be stated thusly: How can you maintain the personal touch of top management in a situation where literally scores of intermediate supervisors had been placed between top management and the rest of the employees?

The answer, in the view of Packard and Seligson, was to indoctrinate as many supervisors and managers as possible in the basic philosophy and objectives of top company management. A pilot program was set up. Its purpose was to train leaders for the future full-scale personnel and general management program.

Twelve top supervisors were selected for training as conference leaders. In 15 sessions of two hours each, held twice a week, the men were taught the principles of conference leadership, as well as the subject matter to be put across to lower-echelon supervisors.

In September 1959 the program started full swing in the manufacturing department, where expansion has been most feverish. Six groups of approximately 16 supervisors each were formed and each was assigned two conference leaders from among the 12 men who had taken the pilot course.

The first round ended last January, and in March a second group of 100 supervisors began the program. Second round, which includes improvements on the original program, will conclude by the end of this month.

What will the program eventually do for H-P? Says Seligson: "We do not expect to get merely a group of charming supervisors. But we can help our people to grow on the job, develop new managers, in-

Zitelli Receives Varian Appointment

Louis Zitelli has been named manager, klystron development, at Varian Associates, Palo Alto, Calif. He joined Varian in 1950 as a research engineer, and in his new post will be responsible for advanced development of all Varian klystrons.

Zitelli was a research assistant at Stanford's Electronics Research Laboratory for four years before joining Varian. In his new position he takes over the post formerly held by Richard Nelson, who was recently appointed head of Varian's Tube Division research and development at Palo Alto.

Appoint Dryden V-P, Engineering

Pearce-Simpson, Inc., Miami electronics manufacturer, announces the appointment of Robert E. Dryden as vice president, engineering. He will head the new R&D division of the company.

Dryden was formerly director of the instrumentation division of Radiation, Inc., Orlando, Fla. Under his direction, Pearce-Simpson will establish a complete research and development division devoted to the field of military and commer-

MAY 13, 1960 - ELECTRONICS
Over White Sands, New Mexico, a killer searched the skies for its target — and found it. With deadly accuracy Raytheon's HAWK missile delivered a lethal blow to another supersonic missile in flight.

Development of Army's HAWK "killing power" by Raytheon's Missile Systems Division, made possible this first successful interception of one missile by another. And today, as a vital part of one of the world's largest electronics companies, Raytheon continues to make significant contributions to the art of missilery. The exciting new Pin Cushion Project for the selective missile identification and the continually being improved Navy's air-to-air SPARROW III are examples of their outstanding creative work.

We are now seeking talented, qualified people to maintain Raytheon's leadership in this challenging field. Raytheon's Missile Systems Division creates a climate for talent — perhaps your talent.

PRODUCT ENGINEERS . . . experienced in electronic packaging with knowledge of production techniques in sheet metal and electronic equipment. Will design electronic portions of guided missiles, radars, computers, test equipment.

SYSTEMS TEST ENGINEERS . . . to evaluate all test equipment design . . . tests to be performed . . . methods used to perform them. An in-plant position with all the challenges of field work. Full authority to smooth out trouble spots. Ultimate responsibility for all parts of all missiles working properly. B.S.E.E. or equivalent with plant or field experience in missiles, radar, or complex fire control systems.

Please send resumés or letters to: Mr. Robert T. Hodges, Employment Manager, Missile Systems Division, Raytheon Company, Andover Plant, Andover, Mass.

...creates a climate for talent.

Bourns Adds to Engineering Staff

APPOINTMENT of James A. Hyams to the engineering staff of Bourns, Inc., Instrument Division, Riverside, Calif., has been announced. He comes to Bourns from Canadair, Ltd., of Montreal, where for the past 21 years he has held the position of design engineer.

Hyams’ assignment will be in linear motion potentiometer group where he will be active formulating new designs for miniaturized instruments.

Control Hires W. J. Bradburn

APPOINTMENT of William J. Bradburn as a senior engineer has been announced by Control, a division of Magnetics Inc., Butler, Pa., producers of static-magnetic components for industrial control systems. He joins Control from the Louis Allis Co., Milwaukee, Wisc., where he was a development supervisor in the firm’s control engineering department. He was with the company for eight years.

At Control, Bradburn will concentrate on the design of industrial control systems utilizing the company’s standard lines of magnetic
amplifiers, saturable reactors, and other associated static devices.

Carlson Takes New Position

APPOINTMENT of William K. Carlson as planning and controls manager for the Semiconductor Division of General Instrument Corp. is announced.

Carlson had been with the Raytheon Co. of Waltham, Mass., for nine years. Most recently he was associated with the Raytheon Semiconductor Division in various assignments in production management, planning and control. In his new General Instrument post, he will be responsible for planning and scheduling of production at the company's Semiconductor Division facility at Newark, N. J.

Lindenberg Joins Astatic Corp.

THE EXECUTIVE COMMITTEE of the Astatic Corp., Conneaut, Ohio, recently appointed Theodore Lindenberg director of engineering. He will direct the company's research, design, development and product engineering program.

Prior to joining Astatic, Lindenberg served as chief engineer of the Pickering Co., Plainview, L. I., N. Y., and was an engineer with the Fairchild Recording Equipment Corp., New York.

He developed and is the owner of over 20 patents in connection with audio equipment. He is a past president and member of the board of governors of the Audio Engineering Society.
THREE TOOLS FOR QUALITY CIRCULATION

Members of a select group, the readers of electronics

As fast as subscription orders are received they are examined individually—by Hugh J. Quinn, Circulation Manager, who stamps each card:

ACCEPTED — to indicate a subscriber is actually engaged in research-design/production/management as a maker or user of electronics equipment.

QUESTIONNAIRE — to delay acceptance until information concerning the subscriber—his function, his company, his title are definitely known.

REJECTED — whenever the order indicates that the individual is NOT within the editorial field of the publication.

electronics is a member of a select group too—The Audit Bureau of Circulation publications—comprised of those magazines and newspapers whose publishers believe that a reader's interest in a publication is best demonstrated when he pays to receive it—those publishers willing to submit to exhaustive periodic audits in order to prove that their circulation is among those individuals they are pledged to serve, and among screened selected individuals ONLY.

The Electronics Man "buys" what he reads in...
Within three years Hermes Electronics Co. has become the nation's leading producer of frequency selective devices utilizing piezoelectric crystal resonators. The growing demand for crystal filters and related devices has created a number of career opportunities for: Circuit Design Engineers, Crystal Physicists, and Network Theory Specialists.

Hermes Electronics Co. is a unique organization where responsibility and initiative are encouraged. Here you will also find the stimulation and environment of a young and growing company. Your association will be with staff members who are in the vanguard of many of today's rapidly expanding technical frontiers.

Salaries and other benefits are comparable to those of major research and development organizations. The company's location in Cambridge, Mass. affords unequaled cultural, living, and recreation facilities.

Liberal educational benefits are allowed for graduate study at leading universities in this area.

Interested scientists and engineers are invited to address inquiries to: Mr. E. E. Landefeld, Personnel Director.

**DIVERSIFIED ENGINEERING!**

*in R&D Department at Electric Boat Division of General Dynamics*

**SYSTEMS ENGINEERS**
To perform conceptual engineering and systems analysis on complex electromechanical and hydraulic systems, co-ordinate the technical efforts of detail engineering, and perform customer technical liaison.

**ELECTRICAL ENGINEERS**
To perform system analysis for determination of servo requirements, particularly for large horsepower applications; and to design special-purpose electronic circuits for use in control, computation, measurement, and communications areas.

**SYSTEMS EVALUATION ENGINEERS**
To perform conceptual engineering and production engineering of electronic equipment with particular regard to circuit development.

MITRE is an independent system engineering corporation formed under the sponsorship of the Massachusetts Institute of Technology. Its task is to provide technical solutions to the varied and complex problems inherent in all types of large-scale command and control systems.

An integral part of this system engineering activity is an active program of advanced experimental development carried on in conjunction with system design, analysis, integration and evaluation.

Engineers and scientists with an interest in both development and analysis work are invited to join MITRE's expanding scientific community. The convenient location in suburban Boston affords excellent opportunities for graduate study under a liberal educational assistance program.

To learn more about these positions, write in confidence to

Vice President - Technical Operations

THE MITRE CORPORATION

Post Office Box 31, 17-WF - Lexington 73, Massachusetts

A brochure more fully describing MITRE and its activities is available upon request.

SEARCHLIGHT

Equipment Locating Service

NO COST OR OBLIGATION

This service is aimed at helping you, the reader of "SEARCHLIGHT", to locate surplus new and used electronic equipment and components not currently advertised. (This service is for USER-BUYERS only).

How to use: Check the dealer ads on pages 146, 147 & 148 to see if what you want is not currently advertised. If not, send us the specifications of the equipment wanted on the coupon below, or on your own company letterhead to:

Searchlight Equipment Locating Service
c/o ELECTRONICS
P. O. Box 12, N. Y. 36, N. Y.

Your requirements will be brought promptly to the attention of the equipment dealers advertising in this section. You will receive replies directly from them.

**ELECTRONIC SYSTEMS DEVELOPMENT**

Are you interested in investigating the application of electroluminescence, photoconductivity, solid state, or other new electronic principles to small electronic systems? Your work will be to determine which of these areas merits further development. You will be directing the work of a small group of engineers and technicians. A Ph.D. degree in physics, electronics, or electrical engineering is desired, but an M.S.E.E. with solid experience in relevant areas will be considered.

Please write, outlining briefly your background and experience, to:

Mr. A. J. Ronvaux, Dept. 554Q2
IBM Engineering Laboratory
Lexington, Kentucky

---

**DEPARTMENT OF COMMERCE**
**NATIONAL BUREAU OF STANDARDS**

Electronic Engineer. To direct the development, operation and maintenance of the instrumentation for the National Bureau of Standards' electron accelerators, betatrons, synchrotrons, and high intensity linear accelerators. Familiarity with pulse circuitry necessary; experience with high energy accelerators and radio frequency power supplies desirable. Career Civil Service position—$8810 or $10,130, depending on experience.

Apply to:
Dr. H. W. Koch
Chief, High Energy Radiation
National Bureau of Standards
Washington 25, D. C.

---

**SALES ENGINEERS**

We are plotting on the market several new products including recording and controlling instruments and require Sales Engineers for our Houston, St. Louis, Chicago, Detroit, and Cleveland districts. Prefer Electrical, Mechanical, or Chemical Engineers. Can offer excellent opportunities for qualified men. Successful candidates will be given a factory course at Waterbury before assignment to one of the above districts.

Write Mr. H. E. Beane, Vice President,
THE BRISTOL COMPANY
Waterbury 20, Connecticut

---

**ELECTRONIC ENGINEER**

Opening in growing concern located in university town in southwest. 2 to 8 years experience in circuit design, telemetering, transistor, or data handling required. Pleasant working and living conditions.

DORSEY ELECTRONICS LABORATORIES, INC.

Norman, Oklahoma

---

Key opening on important new projects at IBM

**ACF ELECTRONICS DIVISION**

**ELECTRO-PHYSICS LABORATORIES**

Responsible assignments in furthering the state-of-the-art of Ionospheric Physics, combining competitive salaries and unusual growth potential, are offered to men who can contribute. Our present needs are for:

**Electronic Engineers**

**Field Station Engineers**

For Research Programs in Ionospheric Propagation & HF Communications

**SENIOR DEVELOPMENT ENGINEERS**

Advanced degree in E.E. or Physics preferred. Must be familiar with present state-of-the-art in the design of advanced HF receivers and transmitters and possess working knowledge of modern HF networks employing ferrites and magnetic tape cores. Strong theoretical background in modern linear circuit theory desired. Will carry out laboratory development and implementation of new HF communication systems.

**SENIOR ELECTRONIC ENGINEERS**

Advanced degree in E.E. preferred. Must be familiar with conventional pulse circuit designs and applications. Technical background should include substantial experience in data process and data recovery systems using both analog and digital techniques. Knowledge of principles and application of modern information theory including correlation techniques helpful. Will be responsible for the design of sub-systems.

**JUNIOR ELECTRONIC ENGINEERS**

To assist Senior Engineers and Scientists in the development of HF communications and data process equipment. Should have formal electronics schooling and 2 years' experience in circuit design, checkout or analysis of HF communications. Radar Pulse, Analog/Digital or Data Recovery equipment. Construction of prototypes of new and interesting equipment and design of individual components of communications and data processing systems will comprise the major efforts of selected applicants.

**FIELD STATION ENGINEERS**

B.S.E.E. or equivalent, consisting of combined civilian or military technical school, with work experience. Presently employed as a field engineer or project engineer with valid 1st or 2nd Class FCC license and a good command of some of the following: Radar, preferably high power; HF long-distance communications systems; Tropospheric or Ionospheric scatter systems. Must be willing to accept assignments in areas where dependents are not permitted for periods of up to one year. Differential paid for overseas assignments.

The Electro-Physics Laboratories are located in the suburban Washington, D.C. area, where post-graduate study is available in several nearby universities. Housing is plentiful in attractive, well-established neighborhoods. Our relocation allowance is liberal.

All inquiries will be held in strictest confidence and answered promptly.

5067497 Delco PM 27 VDC 6000 rpm 375.00

400 CYCLE PM GENERATOR

Mfgd. by General Electric Co. Model 1A-12 120/208 volts. 400 cycle, 1 or 3 phase, 1 kw. 6.8, rpm 8,000. Approx. dim. 6" x 5 1/2" Internal split drive. Price $100.00

400 CYCLE 1/3 PHASE GENERATOR

MINNEAPOLIS-HONEYWELL RATE GYRO

(Control Flight)
Part no. JG7050A, 115 volts, 3 phase, 400 cycle, single phase potentiometer take off resistance 550 ohms. Speed 21,000 rpm. Angular momentum 250 ml. Con sec. Weight 2 lbs. Dimensions 3 7/32 x 3 29/32 x 3 31/64. Price $32.50

HONEYWELL VERTICAL GYRO

MODEL JG7003A-1

115 volts, 400 cycles, single phase, 35 watts, Pitch and roll potentiometer pickoffs 900 ohms, 40 watts max. 500 ohms. 200 volts, 400 cycle, magnetic momentum 150,000 g.cm 1/3 sec. Erection system 27 VAC, 400 cycles, time 5 min. to 1/2. Weight 3.5 lbs. Price $350.00 each

**Specify Angelica Uniforms**

Wherever utmost cleanliness is a must, Angelica is the scientific choice! Engineered "down to the last thread" for full protection of delicate assemblies, Smooth monofilament fabrics create no lint—Angelica's superb tailoring allows none to gather, Acid-resistant and static-free fabrics in styles for every job—comfortable, easy to launder, long wearing.

Whether you rent or buy, your Angelica representative will help you, as he has others—to choose the right garments for your needs.
Now 2 to 3 week delivery on popular BUORD* items...

and in production quantities!

Shortly after Waterloo, the Duke of Wellington received a letter, postmarked St. Helena. It was from Napoleon. It read: "Excellency: I was amused to hear your recent remark that 'The Battle of Waterloo was won on the playing fields of Eton.' To have won an engagement in Belgium from a field in England, you must have been further back of the battle lines than I thought.

"The real reasons for my defeat were two, and Eton was neither. In the first place, the radar broke down for two hours in the heat of battle. Not even a Napoleon can be expected to make radar work without Bomac tubes.*

"But I might easily have defeated you, faulty tubes and all, had I not been persuaded to partake of a bottle of Scotch on the evening before the battle. I have reason to suspect my drink was tainted. At any rate, on the day of Waterloo, I did not display my usual energy and decisiveness.

"It appears, in short, that you owe the battle to a bottle. (Signed, N.)"

The Emperor received a brief reply by return boat. It read: "Excellency: In view of the fact that your loss at Waterloo appears to have been less a matter of Eton than of Drinking, I am withdrawing my original statement. I have released the following in its place, which I here submit for your approval:

'You can mix Scotch and Water And Water and Scotch But don't whatever you do Make the mistake Napoleon did, And mix Scotch and Waterloo.'

(Signed,) Wellington."
The transistor that helped build an industry...designed, built and introduced by RCA...chosen by top manufacturers for the finest computers...the RCA-2N404 has set new standards of reliability for transistorized computers.

Outstanding new achievements of operating reliability, long life, and stability are being made by the RCA-2N404 germanium p-n-p medium-speed switching transistor. Stringent long-term life tests and dynamic in-circuit performance checks, both at maximum ratings, provide additional proof of the bedrock reliability of the RCA-2N404.

Here are the results:
(1) Representative samples of the RCA-2N404 computer transistor have now passed 12,000 hours of operating life at maximum ratings. The curves at the right show the remarkable stability of transistor parameters over this exceptional time period.

(2) Samples from every lot of RCA-2N404 transistors are tested at maximum ratings for 1,000 hours. During 1959, almost 6,000,000 transistor test-hours at 85°C junction temperature were logged.

Why not call your RCA Field Representative today for the full story on the RCA-2N404 and the RCA-2N404 designed to meet military specification MIL-T-19500/20 USAF. For technical information write RCA Commercial Engineering, Section E-19-NN-2, Somerville, N. J.
