PACENT Parts and Accessories Meet Every Radio Requirement

In specifying or using radio parts and accessories made by Pacent, you have the satisfaction and confidence in knowing that they represent the most advanced engineering design and are of unquestioned quality.

Among the leading Pacent products that are the outstanding popular choice of engineers, experimenters or radio listeners are the Pacent Transformers used by several of the leading set manufacturers and designed in a full and complete line including push pull, filament, and power and the famous audio transformers for present day and amplifying requirements; the Pacent Balanced Cone which has established new standards in radio reproduction and the Pacent Phonovox which utilizes the radio set to electrify a phonograph—the biggest sensation of the year.

Pacent products may be obtained at all good dealers. Write for descriptive literature on the items you are interested in.

Igranic Electric Co., Ltd., Bedford, England
OUR SERVICES ARE AT YOUR COMMAND

The pioneer house of Continental is glad to place its extensive merchandising facilities at the command of the buyers, engineers, and other members of the Radio Club of America. Through this dependable service, built up during years of steady growth, Continental is able to recommend members to reliable dealers in their districts or to arrange for their securing such radio materials and merchandise as they need.

The names of dealers in your vicinity and any other information you may desire will be cheerfully supplied on request.

Application of the Four-Electrode Receiving Tube (UX-222)

By Alan C. Rockwood

and

B. J. Thompson

Research Laboratory, General Electric Co.

A Paper Delivered before the Radio Club of America, February 8, 1928

PART II

It will be of interest to consider the actual performance of the UX-222 and to compare this with the UX-201-A. At broadcast frequencies in carefully designed amplifiers using the UX-222 amplifications of 40 to 50 per stage have been obtained with complete stability. With the UX-201-A in neutralized circuits and with the best transformers, an amplification of about 10 per stage is the practical limit. At a frequency of 20,000 kilocycles (15 meters) amplification of 10 to 15 per stage is obtained from the UX-222. It is practically impossible to operate the UX-201-A as a radio-frequency amplifier in the short-wave bands, because of oscillation even with careful neutralization. In the intermediate frequencies, 40 to 100 K.C., amplification from 100 to 150 per stage may be obtained from the UX-222 while 20 to 40 is the best that may be done with the UX-201-A.

While 45 volts is the recommended voltage for the screen-grid tube for all such uses as those just described, increasing it to 67.5 volts will usually result in a slight increase in amplification although this is not advised in most cases as it results in increased plate current. While 90 volts will usually be a satisfactory plate voltage, the use of 135 volts results in increased amplification and better performance; this voltage should not be exceeded. In nearly all cases a negative control grid bias of about 1.5 volts should be used.

Where resonant impedances are used in the load circuit the plate resistance of the tube operating into the load acts as a shunt across this load, and hence affects the sharpness of the tuning, or the selectivity. The UX-222, with a plate resistance of 85,000 ohms, acts as a very high resistance shunt, and consequently gives greater selectivity than a tube having lower plate resistance.

Another important use of
the UX-222 as a screen-grid tube is in resistance-coupled amplifiers. Here again it is possible to realize considerable amplification by the use of high impedance loads, while the low feed-back capacity makes possible amplification at higher frequencies than with three-electrode tubes.

It must not be supposed, as might at first seem the case, that by using an 800,000-ohm resistance in the load circuit, an amplification of 150 per stage will be obtained. To do this would require over 1500 volts B supply due to the high d.c. voltage drop in the load resistance. By examining Fig. 15, the effect of this will be seen. This diagram presents a family of plate characteristics of the UX-222 taken at 45 volts on the screen. If it be assumed that the B supply voltage is 180 volts and that the load resistance is to be 250,000 ohms, the line A—B represents the voltage-current curve for the load, passing through zero current at 180 volts. The intersection of this load resistance line with the plate characteristic of the tube indicates the operating voltage and current of the tube for the grid bias corresponding to the curves used. It will be seen that, with all biases of less than 4.5 volts negative, the tube operates at such a low plate voltage that the amplification factor is negligible. With negative 6 volts bias on the control grid the mutual conductance of the tube has dropped off so much that the amplification is only about 40 per stage.

Fig. 16 shows a similar family of curves taken with 22.5 volts on the screen. It will be noticed here that the tube operates satisfactorily with only 1.5 negative volts grid bias. Under these conditions, the amplification is again about 40 per stage.

Fig. 17 shows an equivalent circuit for a resistance-coupled amplifier. Here:

\[ C_G = C_{gs} + C_{gs} + C_{gs} \]

when \( C_{gs} \) is the plate-grid capacity of the tube, \( C_{ps} \) the plate-screen capacity, and \( C_{fs} \) the plate-filament capacity, all including wiring capacities. Also:

\[ C'_G = C'_{gs} + C'_{gs} + C'_{gs} (A + 1) \]

where \( C'_{gs} \) is the capacity between grid and screen of the next tube in the amplifier, \( C'_{gs} \) the grid-filament capacity, \( C'_{gs} \) the grid-plate capacity, and \( A \), the voltage amplification, all of the next tube. \( C \) is the blocking condenser, while \( R_1 \) and \( R_2 \) are the plate and grid coupling resistors. The value \( C_G \) is the effective grid capacity shunted across the load resistance of the preceding stage and serves to reduce the amplification of the high frequencies, due to its bypassing effect. The gain in fidelity due to the reduction of the effective grid-plate capacity of the amplifier tubes will be appreciable. The UX-222, for example (\( C_{gs} = 0.025 \) mmfd. max.) will have a value for \( C_G \) of 9 mmfd., compared with that of 200 mmfd. for the UX-240 (\( C_{gs} = 9 \) mmfd.).

It must be understood that these capacity values neglect the external portion of \( C_{gs} \) due to capacity coupling between the plate and grid circuit wiring. It is easy, unless care is taken in laying out the parts, to set up an audio-

frequency amplifier that will have an input capacity of 50 to 100 mfd. as a result of a $C_{pe}$ of approximately 1 mfd. in the circuit external to the tubes. In Fig. 18 is shown a comparison of two such amplifier circuits using the same open layout in each case with reasonable precautions to avoid coupling between tubes. The improvement in fidelity resulting from the characteristics of the UX-222 is evident, as well as is the increased voltage amplification. If greater fidelity is desired the use of shielded amplifier stages is desirable.

Fig. 19 is a circuit diagram for a two-stage amplifier using UX-222's with a UX-171 output tube. The voltages and constants given in Table No. 2 (page 42) are recommended for ordinary audio amplifiers. Increased amplification may be obtained by using a higher B-supply voltage and making the proper adjustment of the screen voltage.

Resistance-coupled amplifiers for special purposes have been built using the UX-222, and then give satisfactory amplification at more than 50,000 cycles.

AS A SPACE-CHARGE-GRID TUBE

SPACE-CHARGE-GRID tubes are the result of the work of Langmuir in this country and by Schottky and Barkhausen abroad. While, as before mentioned, the UX-222 was not designed primarily for this purpose, it may be operated as a space-charge tube with satisfactory results.

If a two-grid tube is connected, as shown in Fig. 20, with the inner grid at a positive voltage and the outer grid at a negative bias, electrons are drawn away from the filament by the inner grid and thrown out into the space between the two grids. Most of these electrons come to a stop very close to the outer grid, and then fall back to the inner grid. The ones which fall back are replaced by others, so that there is a continuous cylinder of electrons very close to the outer grid. This has the effect of a cathode placed very close to the outer grid, giving low plate resistance. The amplification factor between the outer grid and the plate is only slightly affected by this, so that the result is high mutual conductance.

Space-charge tubes have been popular in Europe where low operating voltages and a small number of tubes were desired. In America, where there is a demand for the multitube receivers, and where power tube operation of loud speakers has necessitated high plate voltage, there has been little demand for such a tube.

The UX-222 operated as a space-charge tube is somewhat different from many of the European tubes. It is a high amplification factor tube requiring moderately high voltages to operate it. Its advantage is higher gain per stage.
than is practicable with three-electrode tubes, due to higher mutual conductance.

Figs. 21 and 22 give the static characteristics of the UX-222 space-charge tube. They differ little from those of three-electrode tubes, with the exception of the added inner grid current, and the high mutual conductance for a tube of such a high amplification factor.

The UX-222 space-charge tube may be operated the same as any three-electrode tube having high amplification factor. The most important use for such tubes is in resistance- or impedance-coupled audio amplifiers. Such an amplifier is shown in Fig. 23. A B-supply voltage of 135 to 180 volts with a coupling resistance of 0.1 to 0.3 megohm is recommended. Suggested operating conditions and the resulting tube constants are given in Table No. 3 (page 42).

Due to the high capacity between outer, or control, grid and plate, the amplification of such an amplifier falls off at high frequencies. This is shown in Fig. 24, which is a curve of amplification against frequency for the amplifier of Fig. 23 and Table No. 3. The gain in amplification over the UX-240 is also shown.

Over one hundred circuits are known to have been developed using the space-charge tube in various combinations of reflex, double regenerative, and similar circuits. Among these are included a large number making use of the negative change of the space-charge grid current with the plate current upon variation of control grid bias. It is doubtful, however, if the greater part of these circuits produce the results as effectively or economically as less involved circuits using a greater number of lower priced tubes.
ISOLANTITE

A Tried, Tested and Approved Insulator for Greater R. F. Efficiency

ISOLANTITE is a highly refined, scientifically processed ceramic of exceptional merit for high-frequency insulation applications. It is non-porous, low in electrical losses even at extreme frequencies, strong mechanically, and is produced in a wide range of sizes and designs to your specification.

AT YOUR SERVICE

For years the organization of R. H. McMann, Inc., has been engaged in supplying the requirements of radio amateurs and radio broadcast listeners. From spark gaps and glass condensers, to shielded grid tubes and cone speakers, this organization, through its many dealers, has supplied the needs of those interested in radio in all its branches.

Today, more than ever, this organization is prepared to give you the benefit of years of conscientious effort and experience in meeting radio demands. We are at your service. Let us put you in touch with a reliable radio dealer in your territory.
