

## On-the-air or Off-the-air...

This natural extension of your hobby provides a new source of pleasure for your entire family. And with the "know-how" you already have, it is easy to put together a true high-fidelity system that gives thrilling, lifelike music reproduction. Just as E-V microphones and other equipment are widely used in amateur and commercial communications...so have E-V high-fidelity reproducing components and systems achieved high recognition for their outstanding quality. Shown here are a few typical examples.

The Aristocrat. Folded-horn corner enclosure. Designed for E-V or any full-range 12-in. speaker or E-V separate 2-way or 3-way systems. Unusually smooth reproduction down to 35 cps. Selected mahogany veneers. Size: 29-5/8 in. high, 19 in. wide, 16-5/16 in. deep.

> Mahogany Net: \$66.00 Korina Blonde. Net: \$72.00

Model A20C Circlotron Amplifier. Has all necessary inputs and controls for handling a complete highfidelity system. Power output 20 watts rated, 40 watts on peaks. Frequency response  $\pm 1$  db 20-20,000 cps at full 20 watts. Size: 1034 in. wide, 1134 in. deep, 73% in. high. Net: \$110.00 Model 12TRXB Triaxial Speaker. Integrated 3-way speaker system combines E-V 135B Super Sonax, Radax Propagator, and large bass cone with heavy magnet in one compact, concentric assembly. Response 35-15,000 cps in recommended Aristocrat enclosure. With level control for VHF driver. Net: \$59.70

Model 84 Ultra-Linear Ceramic Cartridge. Flat response ± 21/2 db from 20 to 15.000 cps. No preamplifier required. No inductive hum pick-up. No microphonics. High-level output. For microgroove 331/3 and 45 rpm. Model 84D. With Diamond Stylus. Net: \$23.10 Model 845.

## NEW SERVICE-DESIGNED 6BG6-GA

Diameter 24% less than prototype! Seated height 13% less! See X-ray pictures at right for standout design improvements in General Electric's new tube—priced same as the 6BG6-G it replaces!

 Button-stem base gives shorter, better-separated leads, for improved heat conduction and superior tube r-f characteristics.

# For mobile work, choose G.E.'s all-new 6BG6-GA... compact, sturdy, high-voltage tested!

O<sup>NE</sup> tube or push-pull, the 6BG6-GA is ideal for your new mobile or portable rig-final-amplifier or modulator service.

General Electric's new beam power pentode is streamlined in size, and as rugged as they come. The tube takes tough mobile operating conditions in stride. A high peak plate voltage rating means you'll have little or no tube arc-over from voltage fluctuations. To further assure this, *every* G-E 6BG6-GA is factory pulse-tested at absolute maximum voltage. 20-watt plate dissipation per tube helps you get the power you need out of a small rig... and at a budget receiving-tube price. Also, here is a tube specially designed and built to perform, to last—one of General Electric's famous Service-Designed types, which TV technicians coast-to-coast are installing in critical sockets.

Your local G-E tube distributor has the new Service-Designed 6BG6-GA. See him today! *Tube Department, General Electric Company, Schenectady 5, New York.*

# **NOW**... Optional Equipment Combinations for COLLINS KWS-1 AMATEUR TRANSMITTER

Collins KWS-1 incorporates the most advanced design features ever offered in an Amateur transmitter — new compactness, new ease of operation, and optimum performance on SSB, AM and CW.

KWS-1 Transmitter

This new Collins transmitter will soon be available as a complete ready-to-operate kilowatt or as individual sub-units as listed below.

KWS-1K

**KWS-1** Transmitter complete \$1,995.00

• KWS-1K Transmitter similar to KWS-1, less high-voltage power supply and PA tubes	1,225.00
• 32W-1 Exciter and low-volt- age power supply. Also includ- ed are sockets for two 4X150A tubes in shield box to be used if 32W-1 is later converted to	905.00
a kw3-1	695.00
• 367A-2 Power Amplifier Kit includes all components, ex- cept two 4X150A tubes, to con- vert the 32W-1 to a KWS-1	215.00
• 428A-1 High-voltage power supply for KWS-1, completely assembled and wired	700.00
• 428A-2 high-voltage power supply similar to 428A-1, ex- cept supplied in kit form	545.00

32W-1

See your nearest Collins Distributor for additional information.

The enemy attack will allow *no time* for the development of advanced communications systems...*no time* to further perfect electronic equipment for defense or swift retaliation...*no time* to produce more of the vital and dependable equipment made by Hallicrafters during World War II and Korea. Hallicrafters, with a background of over twenty years of electronic "know how," is perfecting and producing secret equipment *now* being used by our Air Force and other branches of the service. The American "edge" over the enemy depends upon Hallicrafters and other "Primary Producers" for the United States Armed Forces.

World's leading exclusive manufacturers of communications radio

4401 West Fifth Avenue, Chicago, Illinois

HALLICRAFTERS FACILITIES ARE NOW BEING USED FOR THE DEVELOPMENT AND PRODUCTION OF: GUIDED MISSILE CONTROL EQUIPMENT • COMMUNICATIONS EQUIPMENT • COUNTER-MEASURE EQUIPMENT • COMBAT INFORMATION CENTER • HIGH FREQUENCY ELECTRONIC EQUIPMENT • MOBILE RADIO STATIONS • MOBILE RADIO TELETYPE STATIONS • PORTABLE TWO-WAY COMMUNICATIONS EQUIPMENT • RADAR RECEIVERS AND TRANSMITTERS (ALL FREQUENCIES) • RADAR EQUIPMENT.

7175 - 7200 Kcs.

# BEST AT NO EXTRA COST!

QRM on Novice frequencies rivals the notorious weekend congestion on 75 and 20 meter fone! You'll have better luck, more completed QSOs if you pick an ODD KILOCYCLE FREQUENCY. Landing on multiples of 5 kcs. is pure murder. That's where PRs come in. You can pick any odd kilocycle frequency you want . . . at no extra cost. Order from your dealer's complete stock. If he doesn't have the particular frequency you want, he can get it pronto. So enjoy the BEST as a Novice . . . reliable, stable, highly active PR Crystals . . . the amateur and commercial frequency standard since 1934. You can't miss on α PR.

## Section Communications Managers of the ARRL Communications Department

**Reports Invited.** All amateurs, especially League members, are invited to report station activities on the first of each month (for preceding month) direct to the SCM, the administrative ARRL official elected by members in each Section. Radio club reports are also desired by SCMs for inclusion in QST. ARRL Field Organization station appointments are available in the areas shown to qualified League members. These include ORS, OES, OPS, OO and OBS, SCMs also desire applications for SEC, EC, RM and PAM where vacancies exist. All amateurs in the United States and Canada are invited to join the Amateur Radio Emergency Corps (ask for Form 7).

In Canada:

THE HALLICRAFTERS COMPANY · Don Mills Road · Box 27, Station R · Toronto 17, Ontario, Canada

# THE AMERICAN RADIO RELAY LEAGUE, INC.,

Is a noncommercial association of radio amateurs, bonded for the promotion of interest in amateur radio communication and experimentation, for the relaying of messages by radio, for the advancement of the radio art and of the public welfare, for the representation of the radio amateur in legislative matters, and for the maintenance of fraternalism and a high standard of conduct.

It is an incorporated association without capital stock, chartered under the laws of Connecticut. Its affairs are governed by a Board of Directors, elected every two years by the general membership. The officers are elected or appointed by the Directors. The League is noncommercial and no one commercially engaged in the manufacture, sale or rental of radio apparatus is eligible to membership on its board.

"Of, by and for the amateur," it numbers within its ranks practically every worth-while amateur in the nation and has a history of glorious achievement as the standard-bearer in amateur affairs.

Inquiries regarding membership are solicited. A bona fide interest in amateur radio is the only essential qualification; ownership of a transmitting station and knowledge of the code are not prerequisite, although full voting membership is granted only to licensed amateurs.

All general correspondence should be addressed to the administrative headquarters at West Hartford, Connecticut.

# "It Seems to Us..."

## FIELD DAY

One Saturday in mid-June of last year, from their homes in Canada, the U. S. and possessions, eight thousand three hundred and eighty persons,<sup>1</sup> who otherwise appeared perfectly normal, disappeared into woodlands, mountains and open fields carrying a little food and clothing and a lot of radio apparatus. There they set up two thousand and twentysix<sup>1</sup> separate transmitter-receiver combinations operating independently of commercial power mains and for a solid twenty-four hours of the ARRL Field Day had themselves a time etching the Kennelly-Heaviside layer indelibly with "CQ FD."

The simple process of subtraction indicates that there were 114,007 bolders of amateur licenses who did not take part in Field Day fun. We think they made a great mistake as any participant in the 1954 event will confirm. But it is a mistake which can easily be corrected — the opportunity will come again this June, on the 25th-26th. And with balmy days here again for most of us, now is the time...

. . Time to find out if Old Man Smith's apple orchard will again be available for an operating site. We've got to try out the generator, to make sure the needle valve isn't gummed up again, and that the gas line isn't about to expire from old age. The tent will have more leaks than last year, but we'll try the paraff.n again and keep our fingers crossed. We take our local public relations seriously, but that new reporter on the Daily Blast may not think a night on a canvas cot contributes anything to the public knowledge. Shall we use an antenna changeover relay this year, or just toss a wire out the window for receiving? We've got to decide whether we'll have a multistation set-up so everyone can operate Sunday afternoon, or stick to one station and keep it busy all night. Bill Jones' XYL will say she doesn't think she wants to provide the grub this year, and then change her mind, as she always does, and put on a magnificent spread. .

So we'd better devote the next meeting to Field Day. And you'd better, too. First thing you know it will be time to put up the antennas, and then you'll suddenly remember

And probably many more not reported to Hq.

that one of the masts got broken when somebody let go of a guy wire last year. And that table leg needs fixing again. So, you see, if you don't get busy you're liable to miss all the fun — and have only yourself to blame.

We think FD is the top event of the amateur year. Where else, in one week end, can you combine the good-fellowship of a hamfest, the underlying motive of preparation for public service, the fresh air and fun of a picnic, the teamwork of coöperative effort, and the excitement of an operating contest? If you haven't tried it before, make it *this* year. BCNU/1!

## MOBILE SAFETY

For some time now we've been on the verge of reminding amateurs of the importance of careful driving during mobile operations, a responsibility accented by the growing number of states which issue call-letter license plates. "Lighthouse Larry" in *G-E Ham News* last summer stated the case so nicely, however, that we can't do better than commend to your serious attention the following excerpts from his editorial:

. . The license plate program has met with considerable success throughout the nation — and has given us a great boost in publicity. In many cases we are thus put on a level with doctors and other public servants.

However, as we attain this stature we also have to remember that it behoves us to live up to our new standing — by added care and courtesy on the road. Need more be said than to comment that every traffic ticket a ham with call-letter license plates gets is a black eye for ham radio? And suppose through our carelessness it should be something worse than just a "ticket"? Suppose it's a broken, twisted body of a child on the highway? We see such pictures in the newspaper once in a while. And I fervently hope I never see one which includes a "murder car" bearing ham callletter license plates.

You think this is a painful and unpleasant subject? Sure is, but not half as painful and unpleasant as the real thing. We bring it up in the hopes that a few thoughts now, beforehand, may prevent the real thing from ever happening.

## A.R.R.L. PACIFIC DIVISION CONVENTION

## Fresno, Calif. - May 21-22, 1955

The 1955 ARRL Pacific Division Convention will be held in Fresno, Calif., on Saturday, May 21st, and Sunday, May 22nd, and will be sponsored by the Fresno Amateur Radio Club, Inc. There will be two days of excellent entertainment consisting of a variety comedy program, many outside activities, electronic exhibits, technical discussions, and mobile hunts, mobile judging, and ladies' luncheon and activities, topped off with a barbecued steak banquet. The price for each ticket is \$6.75. For further details address inquiries to: 1955 ARRL Pacific Division Convention, % Grant Storey, W6NTK, 908 West Pico St., Fresno 5, Calif. Preregistration ends May 16th, 12:01 A.M. If you desire to register early, make out your checks to the Fresno Amateur Radio Club, Inc.

## May 1930

... New records set ... all continents active ... excellent reception ... foreign stations craving more U. S. activity! These are the highlights of "International Communications on 28 Mc.," by Clark C. Rodimon, W1SZ.

. . . QST announces the appointment of George Grammer, WIDF, as Assistant Technical Editor. Mr. Grammer, formerly W3AIH of Audubon, N. J., joined the Headquarters staff last fall to take charge of the ARRL Technical Information Service.

. . . Pioneering in the field of air-to-ground communications is still continuing with recent 'phone experiments. A summary of the latest is presented by C. H. Vincent, W8XB-W8RD, in "Airplane Radiophone Communications Experiments."

... In keeping with Mother's Day, the "Old Man" pays a fine tribute to moms (especially those of hams!).

... W4GV is described as a station featuring effectiveness, convenience, and low cost. Operator Cornelius W. Zimmerman pounds the ether with two transmitters putting out healthy signals on 7 and 14 Me. The receiver is a simple, but nevertheless effective, two-stage "blooper."

. . . In "Our Regulations Are Revised." K. B. Warner tells of latest FCC changes in amateur regulations. Among them are the solidification of the amateur's position, better plate supplies required, the 10-meter band made exclusively amateur, and compulsory logkceping.

. . A light, compact, and completely shielded "inhaler" that covers a wide frequency range as well as being selfcontained is described by Howard A. Chinn in "An All-Service Portable Receiver."

# The "Z-Match" Antenna Coupler

Impedance Matching the Easy Way

BY ALLEN W. KING,\* WICJL

"W HEN it takes more time to make frequency changes in an antenna-coupler circuit than it does in a 500-watt rig, it's high time something should be done about it." The quotation is from a 1954 QST that appeared at just about the time the "Z-match" was finished and in operation. Having been a user

Panel view of the "Z-match" antenna coupler. Incorporating a built-in bridge for forward and reflected power and a dummy autenna, it uses a multiband tank in a new circuit arrangement for matching the usual run of transmission-line loads to a coaxial link.

of all-band tank circuits for the past few years, the writer had decided to attempt to use one in reverse, and some interesting results were obtained.

The "Z-match" antenna coupler is designed for use with transmitters having up to 250 watts input, and will match a 50-ohm coaxial line to both reactive and nonreactive loads ranging from

\* Project Engineer, Harvey-Wells Electronics, Inc., Southbridge, Mass. • This comes close to being the ultimate in multiband antenna couplers, from the standpoint of convenience and ease of operation. Using a multiband tank in an ingenious circuit arrangement, it offers switchless 3.5-30-Me. operation plus quick and certain adjustment to optimum coupling by means of a built-in bridge.

10 to 2500 ohms. It covers the frequency range of 3.5 to 30 Mc. without switching coils. One of the most important features of the unit is the fact that all matching is done visually, with a Micromatch type s.w.r. bridge.

Additional features incorporated in the "Zmatch" besides the all-band tank circuit are a 50-ohm dummy load and a power-indicating device that is left in the line at all times, reading either forward or reflected power as selected by a front-panel switch. Two output links are provided, for either low-frequency (3.5 to 7.3 Mc.) output or high-frequency (14 to 30 Mc.) output. A second front-panel control is provided for the selection of various functions. The noninductive 50-ohm dummy load is connected in circuit in Position 1, while the second position switches the transmitter to the coupler proper. Position 3 switches the transmitter to a 50-ohm output connection which is independent of the coupler but allows the use of the power-measuring device when feeding directly into a matched 50-ohm line.

The complete schematic is shown in Fig. 1. Like most homebuilt projects, other parts can be substituted. However, care should be taken in

## •

The multiband tank circuit consists of the split-stator capacitor at the left and the two inductors, with links, in the center. Coupling is controlled by the tank and the capacitor at the right. The two-terminal assemblies connect to the two link coils.

following the layout of the unit, especially the forward- and reflected-power indicating device.

## Construction

The "Z-match" shown in the photographs is built on an  $11\frac{3}{4} \times 9\frac{1}{4} \times 2\frac{1}{2}$ -inch chassis, and the panel is  $12\frac{14}{4}$  by  $6\frac{34}{4}$  inches. These were used because they were on hand, but any number of commercially-available chassis and dust-cover combinations could be used with good results.

The chassis itself is used to separate the lowimpedance input circuits from the comparatively high-Z output circuits, and no matter what size chassis is used this constructional practice should be followed. The coupling capacitor  $C_{10}$  is electrically above ground and is mounted on two feed-through insulators (Johnson type 135-55), one of which is used to bring the electrical connection through the chassis to the rotor of  $C_{10}$ . This capacitor is set back from the panel and coupled to the dial by an insulated shaft, thus eliminating body capacity.  $C_{11}$  is mounted at the other end of the chassis and the control is brought out through the panel with symmetry in mind. Inductors  $L_2$  and  $L_4$  are mounted near the rear output terminal panel, mainly because this is the high-frequency section (14 to 30 Mc.) and over-all lead length should be kept to a minimum. Coils  $L_1$  and  $L_3$  are mounted at right angles to  $L_2$  and  $L_4$  to reduce mutual coupling.

The output terminal panel on the rear of the chassis has two National type FWH connectors and a wing-nutted ground terminal, allowing the operator to connect either balanced or unbalanced antennas. The two output terminals (high and low frequency) could very well be one, if an antenna changeover relay was used, although separate connectors are convenient when separate antennas are used.

The two rotary switches  $S_1$  and  $S_2$  are placed in a position to maintain panel symmetry, and also to keep lead lengths to a minimum for the connections to  $S_2$ . As can be seen from the photographs, the 50-ohm dummy load is mounted on standard fuse clips and the "hot" end is kept as close to the ceramic switch  $S_2$  as possible. The dummy load has been insulated from the chassis at the hot end by a 1/4-inch-thick phenolic block: however, the same feed-through that was used on  $C_{10}$  could be used instead. The grounded end is raised up from the chassis merely in keeping with good constructional practice. This can be done with a metal spacer having the same height as either the phenolic block or the feed-through type insulator, whichever is used.

The rear-view photograph shows the output terminals marked as "parallel" and "series." These, however, could be called "low-frequency"

The bridge assembly. The circuit arrangement is made symmetrical for the purpose of reducing the effects of stray capacitance and inductance. The resistors in the center  $(R_i)$  are assembled in the form of a cylinder supported by soldering their leads to circular pieces of wire. This reduces inductance and tends to assure uniform current distribution throughout the assembly.

and "high-frequency" outputs. The thought in marking them "parallel" and "series" was that the low-frequency tank coil is parallel connected, while the high-frequency tank coil is the series circuit.

## S.W.R. Bridge

The s.w.r. bridge consists of two bridges connected back to back so that incident and reflected power may be determined. The theory and operation have been ably presented elsewhere and will not be dealt with here.<sup>1</sup>

The incident-power bridge consists of  $R_1$ ,  $C_5$ ,  $C_6$  and the transmitter output impedance; the reflected-power bridge consists of  $R_1$ ,  $C_1$ ,  $C_2$  and the load. The output of the bridge is rectified by

<sup>1</sup> Jones and Sontheimer, "The Micromatch," QST, April, 1947. See, also, "Recent Equipment," p. 43, QST, March, 1955. the crystal diodes. A d.c. path is provided by the r.f. choke. The rest of the components are used for r.f. filtering.

 $R_1$  consists of sixteen 10-ohm  $\frac{1}{2}$ -watt composition resistors in parallel. Since the bridge is designed to operate from 3 to 30 Mc., it is important that noninductive resistors be used. For best results,  $C_1$  and  $C_5$  should be of the button type. They proved to be decidedly better than silver micas. Needless to say, all lead lengths should be kept as short as possible to reduce the effects of lead inductance. The layout shown in the photograph should be followed, and since this shows the placement of parts quite clearly, constructional details will be omitted.

In the initial set-up of the bridge, set  $S_2$  to the dummy load position, apply r.f. power to the input terminal, and adjust  $C_2$  for zero deflection. Next, temporarily reverse the bridge and adjust  $C_6$  for zero deflection. Then return to the original input-output connections and the bridge is ready for calibration. A good calibration will require comparison with an already-calibrated power meter, or by calculation from the r.f. current in the dummy load as measured by an r.f. ammeter connected in series with the load. The full-scale power values (three ranges are provided for) may be set by adjusting  $R_2$ ,  $R_3$  and  $R_4$ . However, an actual power calibration is not at all necessary to the operation of the "Z-match," since the bridge will serve quite well both for adjustment of coupling and for *relative* power indications without calibration.

The meter used in the bridge has a basic movement of 0-200 microamperes, and in this case a hand-calibrated scale was made by taking the original meter plate off and reversing it. The three scales were then hand-painted on, as the photograph shows.

### Operation

The bridge provides a visual way of adjusting the coupler, while the 50-ohm noninductive load (Continued on page 116)

Switches, input circuit, bridge and dummy antenna are below chassis. The three variable resistors at the upper left in this view are adjusted for proper power calibration of the bridge and thereafter left set. The Globar resistor used as a dummy antenna is along the right-hand edge.

## **Automatic Mobile Antenna Tuning**

A Self-Resonating System for 40 and 75

BY JOHN A. HARGRAVE,\* WØIGP

**FT** is obvious that mobile operation of the amateur station has increased many times during the past several years. While the 10-, 15and 20-meter bands offer a general efficiency and convenience of operation from a mobile station comparable to that of the home station, 40 and 75 meters present a more difficult problem. This may be attributed primarily both to practical power limitations and poor radiationsystem efficiencies. It has been generally proven that, except for increased physical length, the greatest single factor contributing to the efficiency of a loaded antenna system is loadinginductor efficiency or Q. The greater the r.f. resistance of a given loading inductance, the greater will be the r.f. loss resulting from its operation. It becomes apparent that for a practical figure of efficiency, maximum practical loading-inductor Q must be maintained, and general transmitter and coupling efficiency must be kept at a reasonably high figure.

The expression "high Q" is a relative quantity and strictly dependent on the peculiar interpretation of the user. High Q is generally synonomous with the presence of a sharply resonant circuit with a narrow bandpass characteristic. Generally speaking, a high-Q 5- to 8-foot mobile whip antenna, loaded for the 75-meter band, will be sharply resonant, and will begin to appear seriously reactive at a deviation from the carrier frequency of about 5 kc. Any effort to broaden the response by loading-inductor construction will, in the majority of cases, be merely a compromise

\* R.F.D. 1, New Sharon, Iowa.

• Most mobile operators, especially those working 40 and 75, understand the inconvenience of having to stop and retune the antenna for every few kilocycles changes in frequency. The system described here does away with all this by automatically reresonating the antenna whenever frequency is shifted. It also compensates automatically for detuning caused by antenna lay-back, or opening the trunk.

in efficiency and a most dear one. Much has been written concerning high-efficiency loading inductors, and any basic theories conscientiously applied will in all probability result in an appreciable increase in Q and radiation efficiency.

An increasingly large number of the mobile transmitters being built are for multiband and VFO operation. The majority of these are being mounted beneath the automobile instrument dash, within easy reach of the driver-operator. Mobile VFO seems like a marvelous convenience until it is realized that the carefully designed antenna system is restricted to a bandwidth of a few kilocycles. It is mechanically practical to provide an adjustable whip length or to afford a manually adjustable inductor to enable multifrequency operation, although their location by necessity must be remote from that of the underdash-mounted VFO transmitter.

WØIGP's under-dash mobile installation. The automatic antenna-tuner control box is at the right. The shafts of the two potentiometers extend from the bottom.

Within this article is described a system for use over the 40- and 75-meter bands providing automatic adjustment of antenna resonance in response to the output frequency of the mobile transmitter. It permits maximum use of VFO control and convenient use of maximum-Q antenna systems. This system was installed in the author's 1953 Buick and has proven very successful and a great convenience. The present mobile transmitter runs 40 watts input, but the system has been used successfully with input powers of from 15 to 300 watts. Although the system was designed for mobile operation, it has been used experimentally on a fixed-station vertical and has proven very satisfactory.

### Circuits and Theory

This system<sup>1</sup> consists of a device for detecting antenna resonance, and provides control of a reversible motor which is coupled to a variable antenna-tuning inductance located at the base of the antenna. An inductive load, as observed by the detector, will cause the motor to rotate in one direction, while a capacitive load will cause it to operate in the other direction, such rotation reëstablishing antenna resonance.

It is generally understood that an r.f. transmission line terminated in a pure resistance equal to its characteristic impedance will be flat. This means that there will be no reflections from the loaded end of the line, and that at any point along that line the voltage and current will be in phase. A high-Q antenna may be matched to a given type of transmission line but, should the resonant frequency of the load shift to a slightly higher or lower frequency, or should the exciting frequency change to a lower or higher frequency, the antenna system will no longer present a purely resistive load to the transmission line and a complex load will reflect a standing wave back along the transmission line. Under such a condition a shift in voltage/current phase and amplitude relationship will result. These factors produce an increase in load impedance and a significant drop in transmitter loading. The detecting system operates as a result of these variables reëstablishing a resistive termination.

The phase detector used in this system is quite similar to the Foster-Seeley f.m. discriminator. Operation of the conventional discriminator results from the phase relationships existing in a transformer having a tuned primary and secondary, both capacitively and inductively coupled. The phase detector shown here in Fig. 1 operates from a low-Q impedance, both capacitively and inductively coupled to the r.f. antenna transmission line. This impedance, represented by  $L_2$  and its distributed circuit capacitances, provides sufficient impedance for satisfactory circuit operation and avoids the inconvenience of a tuned tank. As was previously stated, providing a proper match exists between the r.f. load and its transmission line, r.f. current and voltage on such uline will be in phase. The voltage on the line is used as a reference, and a small amount of this voltage is coupled into the detector circuit through the distributed capacitance existing between  $L_1$  and  $L_2$ . The relative amount of this

Fig. 1 — Phase-detector circuit used to produce control voltage for the automatic mobile-antenna resonator.  $E_1$  — Voltage across transmission line.

 $E_2$  — Portion of  $E_1$  determined by the voltage-divider ratio of  $C_1$  and distributed capacitance,  $C_X$ .  $E_3$ ,  $E_4$  — Voltage induced by  $L_1$ - $L_2$  mutual.

 $E_{2-3}$ ,  $E_{2-4}$  — Vector sums of applied voltages.  $L_2$  is selfresonant at a frequency considerably above normal frequencies of operation.  $L_1$  is a  $\frac{3}{4}$ -turn link in series with the autenna and transmission line.  $C_2$  and  $C_3$  provide very low impedance to r.f. currents.

voltage applied to the detector circuit is determined by the capacitive voltage-divider ratio of the distributed capacitance between  $L_1$  and  $L_2$ ,  $C_X$ , and the value of capacitor  $C_1$ . A second voltage, necessary to provide a medium of phase comparison, is introduced as a result of line current flowing through  $L_1$ . Such a current will create a magnetic field about  $L_1$  and, because of mutual inductance, will produce a current and resultant voltage in the secondary coil  $L_2$ . The resulting voltage across  $L_2$  will lag the inducing current through  $L_1$  by 90 degrees.

The two voltages described above appear in series between the plate of each diode and the center tap of  $R_1$ . Voltages  $E_3$  and  $E_4$  are separated in phase by 180 degrees, with reference to the center tap of  $L_2$ , and are in quadrature with voltage  $E_2$  when a condition of resonance is observed on the transmission line under examination. Under these conditions the effective voltage on the plate of each diode will be of similar amplitude, and will produce a rectified voltage of equal and opposite sign across each half of the load resistor  $R_1$ . The resultant sum of zero volts across  $R_1$  indicates a resonant and balanced condition, as indicated in Fig. 2A.

Fig. 2 — Voltage vector relationships for conditions (A) — when the antenna is resonant, (B) — when the antenna is above resonance, and (C) — when the antenna is below resonance. Voltages refer to Fig. 1.

<sup>&</sup>lt;sup>1</sup> Knoop, "Automatic Tuning of the Antenna Coupler," August, 1952, *QST*; Mezger, "A Phase-Angle Detector for R, F, Transmission Lines," July, 1952, *QST*.

Fig. 3 — Circuit of the automatic mobile antenna tuner.

C1 --- Mica; all other capacitors are disk ceramic.

- R<sub>3</sub> Ohmite type AB.
- R4 -- Wire-wound.

All other resistors 10 per cent carbon,  $\frac{1}{2}$  watt, unless otherwise specified.

In the event of antenna detuning or a change in transmitter frequency, a change in the current and voltage phase relationship along the transmission line will result, and a balanced output from  $V_{1A}$  and  $V_{1B}$  will no longer exist. It may again be said that the reference voltage introduced by the capacitive coupling is in phase with the voltage along the line, but there is no longer a 90-degree phase relationship between this voltage and that developed across  $L_2$  as a result of line current through  $L_1$  and  $L_1-L_2$ mutual inductance. Under such conditions, phase relationships similar to the vectors indicated in Figs. 2B and 2C will result. From this it may be seen that a phase shift in one direction, as a result of a change in the exciting frequency, or a change in the frequency of antenna resonance, will cause the detector to produce a negative output voltage, while the opposite change in frequency or antenna resonance will cause the detector to produce a positive output voltage. Potentiometer  $R_1$  is a balancing control, the proper adjustment of which will overcome circuit unbalances and will provide balanced output.

The complete control circuit is shown in Fig. 3. The 6AL5 phase detector provides a d.c. output voltage of either positive or negative polarity dependent upon the resonant frequency of the antenna system in reference to the transmitter operating frequency. This output voltage is applied to the grid of a d.c. amplifier,  $V_{2A}$ , Fig. 3.  $V_{2A}$  is cathode-coupled, by way of cathode resistor  $R_2$ , to  $V_{2B}$ , and the plate circuits of both sections of  $V_2$  are directly coupled to the grids of

or ryare

- $L_1 = Approx. \frac{3}{4}$  turn No. 16 wire, over center of  $L_2$ .  $L_2 = 20$  turns No. 18 enameled wire close-wound, center-tapped on  $\frac{3}{4}$ -inch bakelite rod.
- center-tapped on §2-inch bakelite rod. 1, 12 — Green and amber §2-inch indicator lamps. K1, K2 — S.p.d.t. plate-circuit relay, 10,000 ohms (Potter-Brumfield LB5).
- $S_1 3$ -pole 4-position rotary switch (Mallory 3234-J).

the control tube,  $V_3$ . In order to provide d.c. voltage amplification, direct interstage coupling is necessary. This arrangement places the entire plate potential of  $V_{24}$  and  $V_{28}$  on the respective control grids of  $V_3$ . Under conditions of antenna resonance, the phase detector provides approximately zero volts output, and sensitivity control  $R_3$  is adjusted to the point where the static plate current of  $V_{34}$  and  $V_{35}$  will not hold relays  $K_1$ and  $K_2$  in the energized position. This adjustment places the cathodes of  $V_3$  at a more positive potential than their respective control grids, this bias being of such magnitude as to approach plate-current cut-off.

Following adjustments of balance and sensitivity, any slight change in phase detector output will cause either  $K_1$  or  $K_2$  to operate, causing the tuning motor to rotate in one direction or the other.

## Matching Antenna to Line

It is necessary that the transmission line from the transmitter to the loaded antenna be made relatively flat if smooth indication and operation is desired from one band edge to the other. This may sound like a difficult task, but the adjustment may be made with very little equipment or effort. It essentially requires that the loaded antenna at resonance present the same load to the transmission line as a noninductive resistor equal in resistance to the characteristic impedance of the transmission line. Providing no more than 20 watts of power is made available at the base of the loaded whip, ten 500-ohm 2-watt

carbon resistors may be placed in parallel to act as a dummy load for RG-8/U cable. The impedance-matching system utilized with this antenna consists of a plug-in coil,  $L_2$ , Fig. 4, mounted on the remote tuning unit, and connected from the input side of the variable loading inductor,  $L_1$ , to the automobile body. A satisfactory adjustment may be made by establishing normal transmitter loading with the dummy load, then switching to the antenna system and, while maintaining antenna resonance, adjusting the matching inductance for identical load conditions. It will be found that a difference of as much as one quarter turn will have considerable effect on loading and the proper impedance match. A 6-turn coil  $1\frac{1}{2}$  inches in diameter, 2 inches long, was found satisfactory for this particular installation when operating in the 75meter band. The circuit for the remote tuning unit is shown in Fig. 4 and a photograph of the unit is also included.

## General Design

This system contains two basic units:

1) The control unit consisting of a  $4 \times 4 \times 2$ -inch box mounted beneath the instrument dash, and containing all detecting and control circuits and components other than the motor, the motor-reversing relay and the impedance-matching and variable inductors. All components associated with the control unit are mounted within the box with the exception of the three vacuum tubes. These are mounted on the rear lip of the unit to afford adequate circulation of air.

2) The remote tuning unit is located in the automobile trunk, adjacent to the base of the loaded whip. It contains the variable series in-

Fig. 4 — Wiring diagram of the motor-driven tuning section.  $L_1$  is the variable portion of the whip loading coil. A variable inductor from a military Command transmitter is used.  $L_2$  is a matching inductor.  $K_1$  is a 6-volt d.c. d.p.d.t. relay (Guardian 200-5). The motor is a 6-volt defroster motor. The antenna terminal should be connected to the base of the whip with the shortest possible lead.  $L_2$  should have a solid connection to the frame of the car. See text for further details.

ductor, impedance-matching inductor, tuning motor and motor-reversing relay.

The front panel of the control unit contains a three-pole four-position rotary switch,  $S_1$ , Fig. 3, and two pilot-light assemblies,  $I_1$  and  $I_2$ . The switch selects the mode of operation, and the two pilot lights indicate the resonant condition of the antenna. When the right-hand lamp,  $I_2$ , is lighted, it indicates an inductive antenna, and when the left-hand lamp,  $I_1$ , is lighted, a capacitive antenna is indicated. Providing the system is properly adjusted, a resistive antenna will be

Motor-driven antenna-tuning unit. The plug-in inductor is the matching inductor shown in Fig. 4. This unit is placed in the trunk of the car, as close to the base of the antenna as possible.

## May 1955

The control unit is assembled in a  $4 \times 4 \times 2$ -inch box. The tubes are mounted at the rear, the antenna and transmitter coax connectors on the side, and the switch and indicator lamps on the front.

indicated by both lamps being extinguished. The three-pole four-position switch utilizes the four positions as follows: (1) off, (2) automatic tuning, (3) manual increase inductance, and (4) manual decrease inductance. During normal operation, the switch will be left in Position 2 except on 10, 15, and 20 meters, where the antenna bandwidth is sufficiently broad that automatic tuning is not necessary. In this case, the switch may be left in the off position. When QSYing from one end of a band to the other, it is not necessary to keep the transmitter on the air while waiting for the antenna to be tuned to resonance. While on automatic position the VFO may be adjusted to the desired frequency, the transmitter output tank adjusted to resonance and note made whether the antenna is inductive or capacitive as indicated by the two pilot lights. The transmitter may then be taken off the air and the control switch placed in one of the two manual positions for an approximate adjustment of the series inductance. The switch may then be returned to the automatic position for an exact antenna adjustment.

## Construction

Inductor  $L_2$ , Fig. 3, consists of 20 turns of No. 18 enameled wire close-wound and centertapped on a  $\frac{3}{5}$ -inch bakelite rod.  $L_1$  is formed of No. 16 wire and consists of a  $\frac{3}{4}$ -turn loop about  $L_2$ . This provides an optimum value of coupling for 25-50-watt transmitters. Although the coupling between  $L_1$  and  $L_2$  is not critical, it should be reduced as higher transmitter power is employed. A slight change of coupling may be found necessary with different installations.

To facilitate construction procedures, the control unit was assembled and wired with both  $4 \times 4$ -inch covers removed. This simplifies the task of assembling and wiring considerably. As an aid to simplification it is recommended that wires be cabled together where practical, even though it may require greater lead length. Where no critical circuits are involved, cabling will greatly limit the congestion which is unavoidable with a unit of this size. Of course, the leads to  $L_1$  and  $L_2$  should be kept short and direct.

The tuning motor was originally an automobile defroster motor purchased at a used auto-supply store for \$1.00. It was disassembled and leads brought out for connection to the d.p.d.t. reversing relay. Six- and 12-volt d.c. motors may be wired in a number of ways. Frequently, the armature is connected between the two fields, and the combination placed in series across the automobile battery. In this case the most simple way to provide a reversal of rotation is by reversing the armature connections in respect to the field windings. In other cases a field reversal may be more simply accomplished.

The gear reduction unit was taken from a PE-101 dynamotor where it was originally used to operate an automatic keyer. The variable inductor,  $L_1$ , Fig. 4, was taken from a military Command transmitter. All other components are of standard manufacture and readily available at most radio supply houses. A simple replacement for the entire antenna tuning unit would be a motor-driven variable inductor which is available commercially.

Power for the automatic mobile tuner is taken directly from the mobile transmitter. The filaments are not switched on or off within the unit itself, but are taken directly from the transmitter filament switch. The unit requires 0.9 amp. at 6 volts and 200-400 volts at approximately 15 ma. Satisfactory sensitivity may be realized with voltages as low as 200, although an increase in  $L_1-L_2$  coupling may be found necessary. Voltages over 400 should be avoided because of possible eathode-to-heater break-down in  $V_{3}$ .

## Adjustment

Provided the antenna system has been properly matched to the transmission line in use, the (Continued on page 118)

# Vertical Multiband Antennas

Two Practical Systems with Coax Feed

BY L. L. TAYLOR,\* W8LVK

• The radiation angle from a vertical antenna will be satisfactory for longdistance work over about a 3-to-1 frequency range if the proper antenna length is used. This article offers a solution to the more difficult problem of feeding such an antenna with coax, without excessive loss in the feeder.

ALTHOUGH there is no simple multiband antenna that provides optimum performance with respect to matching a transmission line, systems can be devised which are compromises and can be made to perform fairly well on several bands. This article describes two such vertical antennas, one of which performs quite well on the 10-, 11-, 15-, and 20-meter bands, the other on the 15-, 20-, and 40-meter bands.

It is pointed out in *The ARRL Antenna Book*<sup>1</sup> that vertical antennas do not make satisfactory

Fig. 1 — Vertical-plane field patterns of vertical antennas for several values of antenna height. The field intensity is expressed in millivolts per meter at a distance of one mile for one kilowatt input. Perfectly conducting ground and zero loss resistance are assumed. From Kraus.<sup>2</sup>

multiband antennas because their angle of radiation increases with frequency. This is true except for the region where the vertical antenna is less than 0.64 wavelength long. Between 0.2 and 0.64 wavelength long the radiation angle decreases as frequency increases. This is shown in Fig. 1, which is a field-intensity plot in the vertical plane of a vertical antenna for three different frequencies. These curves assume zero loss resistance in the antenna and a perfectly conducting ground plane. The actual value of resistive loss in the antenna will merely shrink

<sup>1</sup> The ARRL Antenna Book, page 186, 5th edition.

<sup>2</sup> J. D. Kraus, Antennas, page 317; McGraw Hill Book Co. <sup>3</sup> Edward C. Jordan, Electromagnetic Waves and Radiating Systems, pages 482 and 483; Prentice-Hall, Inc.

Fig. 2 — Input resistance vs. length in wavelengths for vertical antennas of three different length-to-diameter ratios. From Jordan.<sup>3</sup>

the eurves slightly but not distort them. A lossy ground plane such as earth will affect the curves at extremely low elevation angles, which will shorten distances for ground-wave propagation,

Fig. 3 — Input reactance vs. length in wavelengths for vertical antennas of three different diameter-tolength ratios, From Jordan.<sup>3</sup>

<sup>\*319</sup> Summit St., Granville, Ohio.

but will not affect the shape of the curves at angles used by amateurs for sky-wave propagation.

The main objection to an antenna which is operated at different points in this 0.64- to 0.20wavelength region is the radical change in input impedances between the bands where the antenna is current fed and the band where the antenna is voltage fed. By using a simple construction technique the amateur can approximate a cylindrical antenna of low enough length-to-diameter ratio to reduce materially these variations in impedance. Figs. 2 and 3 show the manner in which input resistance and reactance of a vertical cylindrical antenna vary with frequency in the region where the antenna is less than 0.65 wavelength long, and for autenna length-todiameter ratios of 60:1, 100:1, and 5620:1. A length-to-diameter ratio of 5620:1 is equivalent to 30 feet of No. 14 wire.

## Practical Antennas

If the vertical antenna can be erected close enough to the rig to minimize transmission-line losses, the two antennas described here can be made to operate very satisfactorily. Fig. 4 shows a 29.9-foot antenna with a 60:1 effective lengthto-diameter ratio that operates very well on 40, 20, and 15 meters. The current distribution along the antenna at the center of each band is represented by the dotted lines. The values of input impedance, optional series inductance which may be used to cancel out the capacitive component of the input impedance, and the voltage standing-wave ratio with and without the series inductance, are all given for the center of each band. The v.s.w.r. values are for the case where the antenna is fed with 52-ohm coaxial cable. With this antenna the series inductance makes very little difference in cable loss; for example, at 7.15 Mc. the loss in 100 feet of RG-8/U cable without the inductance would be 0.62 db. and with the inductance it would be 0.55 db. At 21.225 Mc. the loss without the inductance is 1.9 db. and with the inductance it is 0.83 db. If this antenna is to be used extensively on 20 meters, the length of the feed line is of special importance. With the 9-to-1 v.s.w.r. which exists on 20 meters, the loss in 100 feet of cable will be 2.3 db. This will have the same effect as reducing a 100-watt rig to about 60 watts. With 50 feet of cable the loss will be

QST for

1.3 db., and with 25 feet of cable it is 0.7 db.

A vertical antenna for the 20-, 15-, 11-, and 10-meter bands is shown in Fig. 5. This antenna is 22.16 feet long with a 100:1 effective length-todiameter ratio. The series condenser for use on 20 meters is relatively unimportant and may be omitted as it only reduces the loss in 100 feet of RG-8/U from 1.2 db. to 0.75 db.; however, on 11 and 10 meters the series inductance should be used unless a very short run of cable is used between the rig and the antenna. The loss on 11 and 10 meters is 3.7 and 3.6 db., respectively, for 100 feet of cable without inductance, and that loss is reduced to 1.2 and 1.0 db., respectively, when the series inductance is used.

## **Construction Notes**

The construction of the antenna is fairly simple, as shown in Fig. 6. The box construction with length D on a side approximates a cylindrical antenna of diameter D. The diameter of the four vertical wires is not critical, but should be

Fig. 6 - Physical construction of antennas.

as large as possible to reduce resistive loss. No. 14 wire is satisfactory and was used by the author, but a larger size would probably be an improvement. Either solid or stranded may be used.

The separators are not critical and may be plastic or treated wood. The spacing of the separators is dependent upon the tension used on the antenna; the more tension used the fewer separators needed. The author used ten separators for each antenna. The spring used at the top to provide the tension was an over-sized screen door spring obtained at the local hardware store.

The series inductances can be wound on any convenient low-loss form, and the size of wire, number of turns, spacing, and coil diameter may be picked to fit the specific installation.

<sup>4</sup> The Radio Amateur's Handbook, page 545, 30th edition; page 543, 31st edition.

The ARRL Lightning Calculator or any available coil table such as the one in *The Radio Amateur's Handbook*<sup>4</sup> may be used to wind the inductance required. The author found that No. 12 wire on a  $\frac{1}{2}$ -inch synthane tube will work satisfactorily. The coils, if used, must be placed in a waterproof box and a stepping relay used to select the correct coil for each band, or to short out the coil(s) where none are required. The author strongly suggests keeping the coaxial cable short, connecting it directly to the antenna and not using any series reactance.

The use of ground radials is important, as with any vertical antenna. It is recommended that 4 or more buried radials be used and that they be more than  $\frac{1}{4}$  wavelength long at the lowest frequency to be used. The author has found that four 50-foot sections of aluminum clothesline running at right angles from the base of the antenna work very satisfactorily. One of these radials runs in one window of the basement of the house, along the basement ceiling and out the opposite window. In addition to the radials, a long (6 feet or longer) ground rod should be driven into the ground at the base of the antenna and connected to the junction of the radials and the outer conductor of the coax.

The antenna may be held up by any suitable means, but the most convenient, in most cases, will probably be a clothesline running between two suitable supports such as two trees, a tree and the house, etc.

It must be remembered that, as shown in Fig. 1, the vertical antenna has a low radiation angle; therefore, don't expect it to perform well at short ranges where a high angle of radiation is needed. The author has a horizontal dipole 35 feet above the ground for use on 40 meters. This antenna outperforms the 40-20-15 vertical when working nearby stations (30 to 200 miles) but when the band is open the vertical puts the dipole to shame.

## Silent Keys

It is with deep regret that we record the passing of these amateurs: W1AHY, ex-1FX, Stephan A. Griffin, Livermore Falls, Mc. W2JBN, Andrew H. Kuhn, Orange, N. J. W4AQN, Harry C. # Six Meters for the Beginner

## Part I — The Nature of the Band

## BY EDWARD P. TILTON, WIHDQ

**EXPERIENCE** on the 2-meter band since Novices appeared on the scene has shown us what makes the wheels go around in amateur radio. Today we find Novices and former Novices almost everywhere, enjoying what the band has to offer. Hundreds started on 2 as WNs or KNs and, liking what they found, have stayed there after graduating to General Class status. This has been fine for 2-meter activity, but in attracting the lion's share of all v.h.f.-minded beginners, the 2-meter band has left its nextlower neighbor, the 50-Mc. band, with very little new blood.

The drive of the newcomer is vital to the growth of our hobby. Wherever he congregates, things happen; there is no substitute for his

boundless enthusiasm. It was with this thought in mind that the ARRL Board of Directors endorsed the proposal to open the 50-Mc. band to Technician licensees. Let's look over the characteristics of this recently somewhat-neglected band, and see what it has to offer the fellow who is just breaking into the game, at either the Technician or General Class level.

## Why Start on 6?

In v.h.f. circles, activity begets activity. Nothing discourages a potential v.h.f. operator more than to listen in and hear no signals. "There's nobody here," he concludes, "why should I go on?" But if he tunes across the band and hears people talking together he concludes that something interesting is going on, and he feels the urge to join in.

What the casual tuncr-inner may misunderstand about the 50-Mc. band, if he finds it unoccupied at the moment, is that it is not always quiet. There are 6-meter men scattered all across the country who wouldn't give up the band for anything else in ham radio. They watch the band constantly. Perhaps you don't hear them for weeks at a time, but they're around. Just let a sign of DX show up and they'll be in there soon enough. Others crawl out from under their rocks for every v.h.f. contest, and disappear promptly again when the party is over.

These are the old-time v.h.f. men, mostly. They have a wonderful time on 6, but their kind of operating is by no means enough to make things interesting for the beginner, or even the casual old-timer. Most hams want merely to talk with someone — and 6 is fine for that too, or it could be if more stations used it for that purpose. In fact, there is probably no better band in all the spectrum for friendly rag-chewing over distances up to 50 miles or more. It may not provide the strongest signals, or the best DX, but it certainly does afford the most consistent communication, within its reliable range, of any band we have.

The 50-Mc. band is in-between territory. It has the reliable coverage of higher v.h.f. bands and, like them, it is almost entirely free of serious interference problems. Yet it is low enough in frequency so that the ionosphere gets into the act now and then, opening the band up for DX that may be international or even world-wide in scope. Essentially, though, it is a local or extended-local band, for the DX is available only a small percentage of the total time each year. DX on 6, then, should be regarded as a spice, added occasionally to a satisfying daily fare, and not as an end in itself.

Even if we ignore DX entirely, the 50-Mc. band has much to interest the beginner. You don't need high power, or a tremendous antenna. You'll never have to peel the signals off in layers to get at the fellow you're trying to work. Equipment is simple to build, and easy to get going. Plenty of operators have enjoyed working on 6 with as little as 5 watts input, and the national average is probably well under 100 watts. Transmitters running more than 300 watts are a distinct rarity on 50 Mc. You may want to build a converter, to get the best possible reception, but a first-class job can be made with as few as two tubes. Circuitry and adjustment procedure are of elementary simplicity, as future articles of this series will show.

## Propagation at 50 Mc.

You'll have more fun and work more stuff on 6 if you acquire at least a nodding acquaintance with the ionospheric and atmospheric factors that affect your coverage. Knowing something of what to expect, and when, is at least half the battle.

One thing you'll notice right away is that signal strength from stations other than locals varies with the weather, and with the time of day. Stronger-than-normal signals, at 50 to 200 miles, and occasional reception up to 300 miles or more, result from bending of the transmitted wave as it passes through a boundary between air masses of differing temperature and humidity characteristics. If warm moist air overruns cold dry air we have the right condition for this kind of bending. It happens fairly often: daily, in fact, in warm weather, especially in areas adjacent to large bodies of water. Air-mass movement on a continental scale (the sort of thing you see recorded on the weather maps) can produce this sort of "inversion" over very large areas.

Good v.h.f. conditions lying along large-scale air-mass boundaries can develop at any season. This helps keep life interesting for the v.h.f. man during the winter months. A likely sign that favorable factors are present is the increasing high cloudiness that follows a period of fair calm weather. The barometer will be fairly high and steady preceding the good period, and it is probable that there will be a slow-moving "low" somewhere a few hundred miles to the west. Signals are usually strongest in the early daylight hours, and around sundown, though varying weather conditions may upset this schedule. Watch the weather maps presented daily on many television stations, or check those appearing in the newspapers, and you'll soon develop the knack of telling when things are going to be better than average on the v.h.f. bands.

Ionospheric DX is less predictable, at the present state of the art, but we know in a general way when it is most likely to show up. The most frequent form results from the reflection of the wave by scattered areas in the E region of the ionosphere, some 50 miles above the earth. It can happen any time, but it is most frequent in the early summer months. There is a less-pronounced period in late December and early January.

Sporadic-E skip, as it is most commonly known, is one of the 6-meter operator's real thrills. Signals appear suddenly, out of nowhere, and frequently rise to amazing strength. They may stay in for only a few minutes at a time, or the band may remain open for hours. Occasionally in June or July there may be DX signals around the clock. Signals are commonly heard over distances of 500 to 1200 miles, though dense ionization may bring the minimum skip distance down to 300 miles, or even less. Multiple reflections also extend the range to as much as 2500 miles, on occasion. It is thus possible for an alert 50-Mc. operator to work all states, and at least ten have qualified for the special certificate award that ARRL issues in recognition of this accomplishment.

Reflections from the auroral region offer another means of working beyond the normal range on 50 Mc. If you see "Northern Lights" on a clear night, aim your 6-meter array in that direction and you're likely to hear the weirdestsounding signals you ever imagined. Voice or any other form of modulation is sure to be badly distorted, and may be completely unreadable,

May 1955

making c.w. the only usable means of communication. Auroral conditions develop most often in the early evening, but they may show before sundown, so you have to watch radio conditions to catch all the opportunities. The distances over which auroral effects are noted extend from a few miles to as much as 800.

Around the peak of the sunspot cycle there is a chance of 50-Mc. DX of world-wide proportions. Between 1946 and 1950 many transatlantic and transpacific contacts were made, and North American stations worked several South American countries on 6. It may seem hard to believe, in these days when 28 Mc. is dead most of the time, and 21 Mc. only partially open, but working international DX was quite a sport on 50 Mc. in the spring and fall months of those years. Distances of 2500 to 5000 miles were common, and contacts were made with as little as 3 watts input! An almost unbeatable record of 10,500 miles was set in 1947.

So you see that just about all the factors that affect lower frequencies influence 50-Mc. communication at times, and in addition, it responds to weather variations. As propagation seldom remains stable for more than a few hours at a time, it is hard to say just what "normal" conditions really are. Perhaps it is better to talk in terms of minimum distances, rather than average, if we want to establish what the potential 6-meter operator may be able to work. Suppose you're going to run 50 to 100 watts input. You don't have room for a big tower, so you're planning to put up a 2- or 3-element rotary that won't stand out among the TV antennas. It will be no more than 50 feet above ground - perhaps less. What can you expect to do on 6?

Unless you're completely surrounded by nearby hills much higher than your antenna, you should be able to work at least 50 miles consistently, with stations similarly equipped. If you have a reasonably open location (not necessarily a high one), so that your antenna "sees" a horizon several miles away, your reliable operating radius should be at least 100 miles, and you should get in some contacts up to perhaps 200 miles when weather is favorable. If you have a hilltop site, and plenty of hams seem to manage it, you will find it possible to keep reliable schedules with well-equipped stations out to 200 miles or more, and 300-mile stuff will not be uncommon.

These very rough figures apply to tropospheric conditions only. Results in aurora or sporadic-E work are affected far less by the characteristics

of your location. In either department, the sharp operator in a "poor" v.h.f. location may do just about as well as his more fortunately-situated fellows.

## Equipment

The 50-Mc. transmitter need not be greatly different from gear used on lower bands. Most currently-used tubes work well on 50 Mc., and only a little attention to layout is needed to make an efficient r.f. section for 6. Any recent edition of *The Radio Amateur's Handbook* will give you practical ideas, or there are units you can duplicate, part for part, if you like.

Receiving may be more of a problem. As most hams buy, rather than build, when it comes to receivers, the lack of suitable ready-made gear has kept quite a few hams from enjoying 6 in recent years. Several commercial receivers have a "50-Mc. band" but few of them do a passable job. There are present indications of a change for the better, but you may have to build your own "front end" if you want to receive as far as you can transmit. If your receiver is the singleconversion variety, and nearly all more than two years old are, it probably won't "have it" for 50-Mc. work, without a converter. A few doubleconversion jobs on the market show fair 50-Mc. performance, but all are in the higher-priced brackets. If your receiver is low- or mediumpriced you're sure to need a converter, even though the receiver dial does indicate 50-Mc. coverage.

Fortunately, construction and adjustment of a 50-Mc. converter need frighten nobody. And if your receiver is in good working condition it doesn't make too much difference if it happens to be 15 years old, or one of the low-budget jobs. The *Handbook* can be your guide as to converter designs, and we have some new units in the works here in the ARRL lab. They will be tailored to the beginner's needs, and you'll be seeing them soon in QST.

The antenna is probably the most important part of the 50-Mc. station. Investment in the antenna system will yield greater returns than time and money spent elsewhere in the 6-meter station. You can work a radius of 25 miles or so with an indoor folded dipole, but you'll never know how much fun the band can be until you put up something better. In these days of inexpensive TV rotators and arrays on every roof, a 6-meter beam is within the reach of almost everyone. Whatever you put up for an antenna, make it rotatable. There is nothing more unsatisfactory, in most locations, than a fixed antenna. It will always be aimed in the wrong direction when your friends on 6 are working something good!

Even if you plan only a single element, arrange to be able to turn it. A dipole works surprisingly well if it can be kept broadside to the desired incoming signal. But if you can put up a good dipole, with provision for rotation, you can add

at least one parasitic element. That first one really pays off, too, and even a 2-element beam will do a real job for you, if it is fed properly. Additional elements are worth the effort, too, if you can manage them. Make the antenna as big and as high as you can. Your *Handbook* gives you all the necessary design details.

## Problems — If Any

With our band at 50 to 54 Mc., and TV Channel 2 at 54 to 60 Mc., it is rough on the 6-meter man when his community gets a Channel 2 TV station. It may be rougher in a Channel 2 fringe area. TV receivers are just not capable of slicing it that thin. But there are many areas that do not have Channel 2 service, and for these the 50-Mc. band is relatively free of TVI problems. If moderate power is used and the rig is designed so as to prevent harmonic radiation<sup>1</sup> there is a very good chance of avoiding TVI entirely.

If some is encountered it is easy to cure. The writer has operated on 50 Mc. consistently since long before television, much of the time with high power, without running into any TVI problems that could not be solved readily. If you live in a 40-family apartment house you may not want to try it, but if you can manage 100 feet clearance from your neighbors' TV antennas, operating on 6 should pose no threat to neighborhood peace. You may have to put a 300-ohm stub on here and there, but unless you're blessed with Channel 2 you'll need nothing more pretentious in the way of TVI-preventive measures than a few scraps of Twin-Lead. Even in Channel 2 areas, the problem is by no means hopeless, as W2IDZ showed recently in  $QST^2$ 

Here, then, is the 50-Mc. picture, presented in the frankest possible terms. As one of the band's long-time regulars, the writer feels with several hundred other die-hards — that anyone who has not given 6 a real try has missed one of the great experiences that ham radio has to offer. We hope that in years to come many newcomers will share this opinion. To help them along the way, we've been working for some time on several transmitters and receivers designed especially for the beginner. You'll be seeing them in forthcoming issues of QST.

# **Easy Shielding for Ninety Watts**

The ''Bandbox'' and a 6146 Pi-Network Amplifier

BY RICHARD L. BALDWIN,\* WIIKE

• This is a neat little package combining Don Mix's "Bandbox" frequency-multiplying unit with a 6146 amplifier using a continuously-variable inductor in a pi-network tank. The construction is such that the unit is self-shielding for TVI — with only one very simple metal piece requiring fabrication.

This RIG has two virtues which should recommend it to those who like to build their own gear. First, it is completely and rapidly bandswitched from 160 through 10 meters, without plug-in coils; and second, it is of a mechanical design that allows a maximum of TVI reduction with a minimum of sheet-metal work.

\* R.F.D. 1, Cumberland Center, Maine.

<sup>1</sup> Mix, "The 'Bandbox' -- A Single-Control Frequency Multiplier," QST, April, 1952. See also p. 52, QST, September, 1952.

## Circuit

An inspection of the circuit diagram, Fig. 1, will show you that there is nothing new and tricky here. The front end of the transmitter consists of Don Mix's "Bandbox," slightly modified electrically by the addition of another switch section so that if a VFO with 160-meter output is available, that VFO output can be applied to the grid of the final tube. It was also modified mechanically to fit this particular layout. The final tube is the popular 6146, with a variable inductor and pi network so that no coils have to be changed when shifting bands.

TVI has been reduced to a minimum by complete shielding, by the use of shielded wire for all d.c. leads, and by appropriate by-passing of all leads leaving the chassis. A coil shield covers the meter, and the only possible "hole" is the socket on the rear panel for the power plug. But all leads there are by-passed and no r.f. can be detected leaking out.

The amplifier is set in a "dish" (see Fig. 3) in a cut-out section of the two back-toback chassis. This view is looking down into the transmitter with the top plate off. The tubes in the "Bandbox" exciter section are at the left.

## Layout

Looking at the transmitter from the front, the exciter portion occupies the left half of the chassis, while the final occupies the right half. The panel controls, reading from left to right, are the bandswitch controlling the exciter, exciter tuning, the meter switch, plate capacitor for the 6146, variable inductor for the 6146, and the switch for the loading capacitors. The meter is in the upper center, while a chart in the upper left attempts to balance the extra counter dial on the variable inductor. Along the rear of the chassis are the coax connector for VFO input, the power socket, and the coax connector for r.f. output.

Looking at the top of the transmitter, we see the tubes for the exciter standing at attention at the left, with the shield can for the meter front and center. The final is set in a "dish." with the variable inductor right in the center, the tube left rear, variable capacitor left front, and loading capacitor switch at the right. In order to obtain better operation at 10 meters and in order to cover 160 meters at all, inductance  $L_6$  is broken up into three sections.  $L_{6A}$ 

Fig. 1 — Wiring diagram of the transmitter. The section above the dashed line is the "Bandbox" frequencymultiplier unit. All resistors  $\frac{1}{2}$  watt unless otherwise specified. Capacitor values below 0.001  $\mu$ f. are in  $\mu\mu$ f. All 0.001- $\mu$ f. capacitors except C7 are 500-volt disk ceramic; others are mica.

Fig. 2 - Power-supply and clamp-tube circuit.

L1 -- Swinging choke, 5-25 henrys, 20-200 ma. (Triad C-31A). Ĩ.a - Smoothing choke, 10 henrys, 200 ma. (Triad

Sa (Centralab 2507).

consists of four turns of B & W Miniductor No. 3009, and resonates in the 10-meter band when  $L_{6B}$  is shorted out by running the contactor all the way down to the end. Operation on 15 meters through 80 meters is accomplished with  $L_{6A}$  working in series with  $L_{6B}$ , with  $L_{6B}$ being adjusted for more and more inductance as we progress from 15 to 80 meters.  $L_{6C}$  consists of 134 inches of B & W No. 3907, which, in conjunction with  $L_{6A}$  and  $L_{6B}$ , will resonate on 160 meters. It was removed for the photographs because it hid too many of the other components. It is customarily supported between the rear terminal on  $L_{6B}$  and the pillar insulator (National GS-3) located at the right rear of  $L_{6B}$ . On bands other than 160 meters it is shorted out by an extra wafer section  $(S_{2B})$  of the loading-capacitor switch.

The circuit of the power supply used in conjunction with the transmitter is shown in Fig. 2. A pair of 816s was used originally, but they generated a hash on 80 meters which would not clear up with any of the combinations of filter tried, and so they were replaced with the single 5R4GY. The clamp circuit is one that has been described several times in recent issues of QST.

The VFO that has been used with this rig has a couple of 6AG7s in a Clapp oscillator and buffer, and is keyed with a Millisec relay according to Goodman.<sup>2</sup>

### Construction

In order to obtain complete shielding, two  $3 \times 8 \times 17$ -inch chassis were bolted together back to back, or top to top, depending upon how you look at it. The Bandbox exciter is then built in the left-hand portion of the resulting

enclosure, exactly as previously described by Mix, except for the extra switch section and except for a mechanical rearrangement so that the dials would line up symmetrically along the panel. The cut-out for the final is 7 inches wide and 8 inches long, and a shelf to support the components for the final hangs down  $2\frac{34}{100}$ inches below the cut-out. Fig. 3 shows the

Fig. 3 — The "dish" for the final amplitier. It is bent from aluminum sheet.

dimensions of this shelf, as its configuration is not clearly shown in the photos.

The 6146 is mounted on a small bracket at the left rear of the shelf. Capacitor  $C_8$  is in front of the tube, mounted on a couple of small aluminum spacers so that its dial will be in line with the others. Between  $C_8$  and the tube are  $RFC_1$  and  $C_7$ . Parasitic choke  $L_5$  is supported between the junction of  $C_7$ - $RFC_1$  and the tube plate cap.  $C_{16}$  is connected to the high-voltage lead at the power plug where the lead leaves the chassis. Coil  $L_{6A}$  shows up poorly in the photos, but is supported by a National GS-3 pillar insulator (mounted to the left and in front of the variable inductor) and the terminal of the variable inductor. It is at right angles to  $L_{5B}$ ,

At the right rear edge of the variable inductor is the GS-3 insulator which normally supports  $L_{8C}$ , and directly behind that is the safety choke  $RFC_2$ . Switch  $S_2$  is at the far right: one section switches the loading capacitors which are clustered to the rear of the switch and the other section shorts out  $L_{6C}$  on all bands other than 160 meters, as mentioned earlier. Just barely visible in the photograph is the coil portion of the harmonic trap  $L_7C_{14}$ .

switch.

The exciter section extends along one end of the chassis, as shown in this bottom view. The bottom of the amplifier dish is at the left. The switch at lower center is the meter

Top and bottom plates are 8 by 17 inches, and are secured by  $\frac{1}{4}$ -inch 6-32 screws spaced every 2 inches around the edges of the chassis. The chassis material is rather light, but if care is used it may be drilled and tapped with good results. Just don't tighten up on the 6-32s too strenuously. The 7-inch panel is held to the chassis by the various tuning controls and panel bearings, and by the bolts which hold the meter and meter shield in place. The meter shield is an ICA No. 1540 coil shield, cut down so that it is only 2 inches high.

The only other piece of mechanical work that is at all unusual is the counter for the variable inductor. At the time this transmitter was conceived the only counters obtainable took up more room on the panel and behind it than was available, and so a homemade counter was contrived using Boston gears Nos. G142 and G148, some G29 pinion wire, two panel bearings, a couple of aluminum brackets, and a surplus dial. Fig. 4 shows the method of assembly. The

Fig. 4 -Sketch of drive and indicator for the finaltank variable inductor. The gears are standard items. •

Miscellaneous small parts in the power supply are mounted below chassis, as shown in this photograph.

counter dial on the panel was taken from a surplus tuning unit, and was mounted by drilling and tapping the shaft on which the G148 spur gear was mounted. Incidentally, the spur gears come with hubs which have to be drilled and tapped in order to allow fastening to the shafts.

Now for a few miscellaneous notes on the construction and wiring. You should do all necessary by-passing and other wiring at the 6146 tube socket before mounting it and its bracket in position. There is not enough room to get down between it and the edge of the shelf with any ordinary soldering iron. A series of 14-inch holes is drilled below the tube in the shelf, in line again in the bottom plate and in the top plate, to provide ventilation for the 6146. The now-standard practice of using shielded wiring on the d.c. leads is followed in this rig, with plenty of bonds to the chassis at convenient points. The meter shunts were wound by trial and error, using a rheostat, battery, and fullrange milliammeters to determine the shunts needed. The shunt for measuring exciter current extends the 10-ma, range of the meter to 100 ma., while the shunt for the 6146 plate current extends the range to 200 ma. No shunt is needed for the 6146 grid current. The panel markings are Tekni-Cals.

## Operation

Adjustment of the exciter has been fully covered by Mix, and so need not be detailed further. It might be mentioned, however, that the exciter worked right from the moment plate voltage was first applied, and the process of aligning it was very simple. Thus, if the specifications in the original article are followed you will have no difficulty with that part of the circuit.

In the final the harmonic trap is adjusted by resonating the  $L_7$ - $C_{15}$  combination to your local TV channel. Do this by shorting the coaxconnector terminals and coupling  $L_7$  to a griddip meter. In my case  $L_7$  consists of three turns of No. 18 wire wound to a  $\frac{1}{4}$ -inch diameter, while  $C_{15}$  is 100  $\mu\mu$ f.  $L_7$  was then adjusted until the circuit hit Channel 6.

The values of the loading condensers were picked by going back to the early articles on the pi network. I had to make no further adjustment, and so in this case blind luck triumphed over science.

The 80-meter band is tuned with all of  $L_{6B}$ in the circuit, 40 is tuned with about 12 turns of  $L_{6B}$  in the circuit, 20 meters with about 7 turns, and 15 meters with about 5 turns. For 10 meters,  $L_{6B}$  is shorted out altogether by running the contactor all the way to the end of the coil. These adjustments could vary depending upon what kind of load your transmitter has to feed.

A word of caution about the 6146 is in order. It appears that this tube is particularly susceptible to overloads, and so you should exercise care not to allow it to operate off-resonance; otherwise, you will soon end up with a tube exhibiting grid emission.

This rig has been used by itself, with an antenna coupler, as a very nifty low-power transmitter. It was used with success during the 1953 and 1954 SS contests, and the 'TV receiver in the next room never knew it was on the air. It has also been used to drive a pair of triodes running a kilowatt input.

Major components of the power supply, which is built on an  $8 \times 17 \times 2$ -inch chassis. The voltage regulator tubes, clamp tube and bias battery are at the right-hand end in this view. The "plate switch" socket beside the 115-volt connector on the chassis lip is wired in parallel with the front-panel plate switch and is for remote control of the plate voltage.

# A One-Tube Receiver for the Beginner

The 6U8 in a Regenerative Receiver

BY LEWIS G. MCCOY, WIICP

• The easiest way to break into the receiver-construction game is to build a regenerative receiver. Here is a "onetube" regenerative receiver that is easy to put together and has performance equal to any in its class. And, after all these years, it has an honest-to-goodness antenna coupling circuit.

JUDGING from the mail here at Headquarters, it would appear that one of the many questions facing the newcomer is whether to buy or build his first receiver and transmitter. The answer to that depends on whether one is interested in just operating or in learning about radio. If you want to understand radio, the only real way to acquire experience is by building your own equipment. At least at the beginning.

This article describes the construction of a simple one-tube regenerative receiver that will fulfill the basic requirements for communications work. The title of the article states that the receiver is a one-tube job. Actually, it uses two tubes in one euvelope — envelope meaning the glass enclosure. The 6U8 is a triode-pentode, and in this receiver the pentode section is used as a regenerative detector and the triode portion as an audio amplifier.

With this receiver it is possible to hear amateur and commercial stations in the 2- to 20-Mc. range. This tuning range will enable the builder to listen to the two low-frequency Novice bands. Also, if one is interested in obtaining code practice, W1AW, the ARRL Hq. station, can be tuned in for its nightly code-practice sessions.

## The Circuit

The circuit used in this receiver differs in a few places from the usual regenerative-receiver circuit. For example, instead of the usual small antenna-coupling capacitor or inductor, provision

was included here for either a series- or paralleltuned antenna circuit. This allows a wide range of coupling adjustments to be obtained, as is often necessary with regenerative receivers.

Referring to Fig. 1, the antenna coil,  $L_1$ , couples the signal to the detector tuned circuit  $L_2C_2C_3$ . The capacitor,  $C_2$ , is larger than  $C_3$  and is used as the "bandset" capacitor — once  $C_2$ is set for a particular frequency range,  $C_3$  is used as the "bandspread" tuning control. To facilitate using manufactured coils, the coil  $L_2$  is tapped to obtain a feed-back or "tickler" winding. Regeneration in the detector is controlled by changing the screen voltage obtained at the potentiometer  $R_1$ . An r.f. filter, using two capacitors and an r.f. choke, is placed in the plate circuit of the pentode detector to reduce r.f. appearing at the grid of the triode audio amplifier. Still further attenuation of r.f. at the grid is obtained through the use of a series resistor and a shunt capacitor right at the grid of the audio stage. To save a little money, the audio coupling choke, L3, is made from an interstage audio transformer with the two windings connected in series. A high-inductance choke could be used here, but the series-connected transformer does a good job and is less expensive.

The headphones are connected directly in the plate circuit of the audio stage, and consequently the plate voltage appears at the terminals you can get an electrical shock here if you aren't earcful. Some receivers eliminate this hazard by feeding the plate through an audio choke and coupling to the headphones through a capacitor, but again in the interest of saving a few dollars this protective feature was not included. In any event, be sure to use "high-impedance" headphones with this receiver — the low-impedance headphones that have been available in surplus will not work well in this particular circuit.

## Construction

The receiver is built on a  $7 \times 7 \times 2$ -inch aluminum chassis, with the power supply mounted on

> Front view of the receiver and power supply. The control at the upper left is the general-coverage tuning, center is bandspread, lower left the regeneration control, and the bottom center the antenna trimmer.

> > QST for

•

Rear view of receiver and power supply showing the placement of parts. The variable capacitor on the left is for handspread and the one on the right for general coverage. The leads from the two capacitors are run through rubber grommets to avoid shorting to the chassis top.

a separate chassis. In order to minimize hum pickup and vibration from the power transformer, it is not advisable to mount the power supply on the same chassis as the receiver. It is not necessary to use aluminum chassis for the two units, but it does tend to make a neater job. The aluminum is easy to work — a  $\frac{1}{8}$ - and  $\frac{1}{4}$ inch drill, plus a small rattail file and hack-saw blade being all the tools that are needed for the job, although two socket punches can be used to advantage and will save you some work.

The first step is to mount the coil and tube sockets. They are spaced 2 inches from the sides at the center of the chassis. Ground lugs should be mounted under the nuts that hold the tube socket and also under the rear nut holding the coil socket. Next, the panel holes are drilled.

Looking at the photograph showing the panel front, the knob at the lower left is the regeneration control, lower center is the antenna trimmer. and the headphone tips are at the lower right. The knob at the upper left is for the generalcoverage capacitor, and the one at the right the bandspread tuning. The dial shown in the photograph is the National type K. This has a rim drive and gives a desirable slow tuning rate.

After the holes are drilled in the panel, it is held in place against the chassis and the four holes along the bottom are used as a template for the chassis holes. A small right-angle bracket to hold the antenna-trimmer capacitor is made from a piece of aluminum. The hole in the bracket should be large enough to clear the rotor of the capacitor, since both the rotor and stator are insulated from the chassis. The trimmer is mounted to the bracket by screws and the insulated nuts on the capacitor frame. The bracket, tie points, and audio choke  $L_3$  can now be mounted in place.

The two capacitors,  $C_2$  and  $C_3$ , should then be

Fig. 1 - Circuit diagram of the one-tube regenerative receiver. See page 138 for parts list.

May 1955

31

installed on the panel. If the Type K dial is used, a template is furnished with the dial assembly to give the correct placement points for the dial and rim drive. When the potentiometer  $R_1$ and the pin jacks are mounted in place, they will hold the panel to the chassis. Be sure to insulate the pin jacks from the panel and chassis with fiber washers. The through-shaft bushing is measured and cut to size, making allowance for the insulated coupler. The receiver is now ready for wiring.

## Wiring

If this is your first construction project, there are a few tips about wiring and soldering that will help you do a good job. First, be sure the end of the wire to be soldered is completely clean of insulation or enamel. Solder should not be depended on to hold the connection. Whenever possible, wrap the wire around the connection before applying solder. Hold the tip of the iron against the work until the work is hot enough to melt the solder. Where most beginners make a mistake is in holding the solder to the iron tip and not getting the connection hot enough for the solder to melt and hold. Don't use any more solder than necessary to make the connection. After a connection is soldered, dispose of the loose bits of solder and wire to avoid short circuits to other connections.

Although it is not shown in the diagram, it is important that a separate ground lead be connected to the rotors of  $C_2$  and  $C_3$  and the lead brought below the chassis to a common grounding point at the tube socket. This will help make the receiver stable and reduce hand capacity.

There are five leads coming from the interstage transformer: red, blue, black, and two green. The red lead and green lead that are directly opposite each other are connected together. After the leads are soldered and taped, the end of the black lead is also taped. These leads are then rolled up and tucked in the corner of the chassis. The remaining blue and green leads then become those used for wiring the seriesBottom view of the two units. At the lower left in the receiver is the interstage transformer  $L_3$ . To the right of  $L_3$  is the antenna-trimmer capacitor mounted on a rightangle bracket. Immediately in front of the bracket is the insulated shaft coupler which connects the throughshaft bushing to the antenna trimmer.

The selenium rectifier in the power supply is visible between the two electrolytic capacitors.

connected transformer into the circuit. One is connected to the junction of the  $0.01-\mu f$ , disk capacitor and the 1-millihenry r.f. choke and the other lead is connected to the B+ voltage terminal.

The Barker & Williamson coils are mounted on five-prong plugs, although only four of the contacts are used. The link mounted at one end of the coil is  $L_1$  and the coil proper is  $L_2$ . To make the tickler tap, a short piece of hook-up wire approximately 3 inches long is soldered to the fifth prong on the plug. The piece of wire is then run through the middle turns of the coil and soldered to the tap point. For the 80-meter coil, the tap is connected to the 8th turn in from the link end. To get the tap wire through the middle turns of the coil, it will be necessary to bend two or three turns of the coil in towards the center of the coil. This will provide sufficient clearance for the tap lead. It is also necessary to bend in the 8th turn to make the tap connection. Be sure that none of the bent turns touches adjacent turns.

For maximum bandspread on 40 meters, it is necessary to remove nine turns from the 40meter coil. The turns are taken from the end opposite the link end of the coil. The tickler tap is made on the 4th turn end from the link end.

To bandspread the 20-meter coil, two turns are removed from the end opposite the link end. The tap is placed on the 4th turn from the link end. In all three coils, the tap lead should be insulated where it passes through the coil turns.

## Power Supply

The power-supply components can now be wired. There are two important points that beginners should keep in mind when wiring the supply. The first is that the electrolytic capacitors should be wired with the leads marked with a minus sign, or negative, connected to the chassis. The plus sign, or positive, connects to the choke leads. Likewise, the selenium rectifier is marked with a plus sign, and this lead is connected to the

(Continued on page 136)

# A Compact Two-Tone Test Generator

Dual A.F. Phase-Shift Oscillators for Modulation Checking

BY ROBERT F. TSCHANNEN,\* W9LUO

• This unit provides two audio frequencies of your choice for checking the performance of a linear amplifier. In case you use any of the various two-tone techniques that require only one audio frequency, or want a low-distortion tone for a.m. testing, just use one-half of the circuit diagram.

THE true performance of a single-sideband exciter and linear amplifier is difficult to predict without a few pieces of test equipment. Probably the most important item of test equipment for this purpose is the oscillograph; however, a most useful and helpful companion unit is a low-distortion audio source — better still, a pair of audio sources.

The "Two-Tone Test Generator" described below is designed to provide two independent low-distortion audio test signals. The unit is small and compact and uses only two tubes. No special components are used in the construction of the unit. If the generator is carefully made and adjusted, the total harmonic distortion can be as low as 0.1 per cent.

#### The Basic Circuit

The basic circuit of a phase-shift oscillator is shown in Fig. 1. Operation depends upon producing 180-degree phase shift in the RC network consisting of three capacitors and three resistors; sufficient gain must be produced by the oscillator tube to make up for the loss in the network. For

\* 412 E. Maple St., Lombard, Ill.

the circuit shown, a gain of 20 times is required to sustain oscillation (Reference 1, bibliography). The frequency of oscillation is determined by the equation

$$f = \frac{10^{12}}{2\pi\sqrt{6}RC} = \frac{10^{12}}{15.4RC}$$

where R is in ohms and C is in micromicrofarads. If the oscillator tube has a gain less than 29, oscillation will not begin; if excessive gain is obtained, appreciable distortion may be produced.

Fig. 1 - The basic phase-shift oscillator circuit.

The phase shift through the network at harmonic frequencies is always less than 180 degrees and in some cases approaches zero. This gives rise to negative feed-back which reduces the gain at harmonic frequencies; therefore, essentially a pure sine wave results. Maximum harmonic reduction occurs at the point where the system is just able to sustain oscillation.

## General Circuit Description

A single 6AN8 tube is used as oscillator and output section for each channel of the generator. The pentode section functions as the oscillator

The two-tone test generator is a compact and inexpensive unit and provides two audio signals of different frequencies and equal amplitudes for testing any type of s.s.b. generator. Distortion is extremely low if proper care is used in adjustment.

proper; the triode section operates as a cathode follower output. A half-wave selenium rectifier followed by considerable filtering provides good d.c. for the oscillators. The complete schematic is shown in Fig. 2.

The 1000-ohm controls in the cathode circuits of the pentode stages are used for controlling distortion. The controls permit adjustment of the oscillator tube gain to the point where oscillation will just be sustained. This also corresponds to the point where minimum distortion occurs. Two additional 1000-ohm controls in the cathodes of the triode cathode followers provide control of outputs from either channel.

Arrangement of parts below chassis. The two oscillator-buffer circuits are identical in circuit but not in component values. The three electrolytic condensers in the power supply are contained in a single can-type unit (Mallory 311.9) thus conserving space underneath.

The R and C component values for the networks shown in the schematic of Fig. 2 are approximately correct for the generation of 400and 1000-cycle tones. Other values are given in Table I.

It is important that the linearity of the cathode follower be good since otherwise distortion may be added by this stage. The use of a low- $\mu$  triode tube such as the triode portion of the 6AN8 permits the handling of higher grid swings without distortion. Since the signal handled is small, the possibility of distortion becomes negligible. The effective output impedance of the cathode follower is approximately equal to

10<sup>6</sup>

 $g_{\rm m}$ in shunt with the cathode resistance to ground (where  $g_{\rm m}$  is the transconductance in micromhos). The output impedance is therefore of the order of only several hundred ohms. This is desirable since output signals may readily be coupled into a combining network without appreciable interaction. The tapped-down take-off point from the plate of each oscillator tube reduces external loading on the oscillator and

Fig. 2 — Circuit of the dual a.f. test oscillator. Resistors are  $\frac{1}{2}$  watt. 10 per cent tolerance, unless otherwise specified. Capacitauce values below 0.001  $\mu$ f. are in  $\mu\mu$ f. Potentiometers are linear-taper 1-watt composition.

 $C_4$ - $C_6$ , inc. — Silver mica, 5 per cent tolerance.

- $T_1 125$  volts, 50 ma.; 6.3 volts, 2 amp. (Stancor PA-8421).

۲

## QST for
also reduces the output level to the point where the cathode-follower grid circuit can handle the signal without distortion.

When used for lowest distortion, the output of either channel is of the order of 1 to 1.5 volts r.m.s. Output levels of 8-10 volts r.m.s. are obtainable if a few per cent distortion is tolerable. The increased output capability is obtained by readjusting the oscillator cathode resistance.

The total "B" current drain of both oscillators and output stages is about 16 ma. Linevoltage variations do not greatly influence the

Fig. 3 — Improper operating conditions are shown by 'scope traces. A — Excessive oscillator tube gain. B — Excessive oscillator tube gain, but not as much as in A. C — Same as B except with change in 'scope sweep speed to facilitate estimating second-harmonic distortion by the degree of asymmetry (X greater than Y). D — Optimum symmetry (X = Y), minimum even-order harmonics, low distortion in output.

oscillator frequency; therefore voltage stabilization is not required. Larger screen by-pass and coupling capacitors do not add particularly to the performance of the unit since fixed-frequency operation is used.

Typical voltage readings taken with a d.c. v.t.v.m. are as follows:

1) B+ at output of filter = +120 to +130 volts.

2)  $E_{sg} = +30$  to +40 volts.

- 3)  $E_{\rm p} = +55$  to +80 volts.
- 4)  $E_{k}$  (pentode) = 0.2 to 0.3 volt.
- 5)  $E_k$  (triode) = 6 to 7.5 volts.

#### Construction

The chassis layout of the phase-shift oscillator is not critical. The entire unit is constructed on a  $5 \times 7 \times 1^{1/2}$ -inch chassis. The grid leads of the oscillator tubes are preferably kept short and dressed away from a.e. supply and filament leads. One side of each filament of the 6AN8 tubes is grounded. The photographs of the chassis will assist the builder in making a suitable layout. The small power transformer is capable of supplying as many as four individual oscillators. If desired, a 6X4 rectifier may be substituted in

place of the scienium rectifier; in this case the 330-ohm 1-watt current-limiting resistor in series with the rectifier may be removed.

Miniature silver mica capacitors were used in the phase-shift networks for compactness; however, conventional micas may be used successfully if space is available. The coupling capacitors  $C_7$  and  $C_8$  may be Hi-K disk ceramic or paper types. Components for the phase-shift network are mounted on terminal strips or boards for rigidity and neatness. The capacitors  $C_1$  through  $C_{\rm f}$  are not visible in the bottom view since they are beneath the terminal strips which are located on each side of the chassis. The controls  $R_1$  and  $R_2$  are located on each side of the electrolytic filter capacitor. The output controls, a.c. switch, and output tip jacks are on the front flange of the chassis. The layout shown will provide good accessibility to nearly all components.

#### Adjustment & Checking

After the wiring has been completed and checked the unit may be turned on and each output observed on a 'scope. If no output appears, adjust the cathode resistor of the oscillator to just slightly beyond the point where oscillation starts.

With the values of cathode resistances shown on the schematic, it should normally be possible to stop oscillation near one end of the control and produce high (but slightly distorted) output near the other end of the control. At the point where the distortion becomes noticeable, the wave will usually have an appearance similar to that shown in Fig. 3A or 3B, which indicates even-harmonic distortion (principally second). If a distortion meter or wave analyzer is available it will be simple to adjust each cathode control to the point where lowest distortion is obtained. Since such equipment is seldom available to the ham or experimenter, a reasonable means of minimizing the distortion is to apply the signal under test to the vertical plates of a 'scope and adjust the horizontal sweep speed until a pattern similar to Fig. 3C is obtained. The distortion control can now be rotated until dimensions X and Y are as nearly equal as possible (see Fig. 3D). In other words, if X and Y are made equal, any asymmetry due to second harmonic distortion is negligible.

# The All-Electronic "Ultimatic" Keyer

Part II — How It Works

BY JOHN KAYE,\* W6SRY

• Part I (QST, April, 1955) of this article described what the key does and how it can be built. Here is the explanation of the circuits and pertinent test data. Part I is required, since it carries the circuit diagram.

Пне electronic Ultimatic is best considered as two separate units, a code generator and a selector-memory-sequencor (SMS). The generator is composed of a time base, two character-generating triggers, and a relay-control tube or an optional d.c.-output tube for direct control of vacuum-tube keyers. The SMS comprises a twin-lever key, two memories, two interlockedsequencor circuits, two multiple-character holding circuits, and two sequence-seizure circuits. This SMS structure is completely symmetrical. One side only will be discussed. Each paragraph concerning it can also serve to describe the other side by substituting "dot" for "dash" and vice versa and considering the corresponding circuit components. Refer to Part I for the circuit diagram. To extend the stability range, gridcurrent loading is used in several places. For this reason, some of the voltages to be cited will differ from those calculated from straight voltagedivider action of resistor strings.

# Time Base

The multivibrator,  $V_1V_2$ , generates a sufficiently-square wave at its cathodes from which  $C_2R_4$  differentiates alternate positive and negative pulses for operation of the generator triggers. 'The "mark/space" ratio of this type of oscillator has been found to be substantially independent of plate voltage over a wide range, and consequently, no voltage regulation is required. The elevated grid return of  $V_1$  provides a mark/space ratio of 45/55 with  $R_3$  at ground, increasing to 90/10 before failure as the arm is moved toward the cathodes. A capacity of  $0.05\mu f$ . at  $C_1$  gives a minimum speed below 5 w.p.m. and a maximum above 100. Heaven forbid anyone turning it loose on me!

#### **Relay Output**

During spacing, the relay is energized because the grid of  $V_3$  is held at ground potential at the junction of  $R_{12}$  and  $R_{13}$ . The normal "back" contact is used to key the external circuit. On "mark" the junction of  $R_{12}$  and  $R_{13}$  drops to -15volts, cutting off  $V_3$ . Relatively heavy spring tension on the relay minimizes armature travel

\*2296 West Nicolet, Banning, Calif.

time. When the grid of  $V_3$  returns to ground potential for spacing, the current through  $V_3$ is sufficient to open the contact promptly. Slower armature travel at this time, caused by the stiff spring, is of no consequence. With 0.004-inch armature travel, this method of relay operation results in practically zero variation in the mark/ space ratio to, fantastic as it may sound, well above 100 w.p.m.

#### Idle Code Generator

 $V_5V_6$  and  $V_7V_8$  are cathode-coupled triggers, with  $V_6$  and  $V_7$  conducting in the idle condition. Voltages of +15 and +12 stand on  $R_7$  and  $R_{15}$ , respectively. When the output is to remain spacing, both sequencors,  $V_{10}$  and  $V_{11}$ , are cut off, with cathodes held at +1.7 and +.9 by  $R_{22}$ and  $R_{23}$ , to compensate for the negative contact potentials in the control clampers  $D_1$ ,  $D_2$  and  $V_4$ . Positive pulses from  $C_2R_4$  are clamped at  $\pm .9$  to the grid of  $V_8$  by  $D_2$  and  $R_{16}$ . The junction of  $R_{10}$  and  $R_{11}$  holds the grid of  $V_4$  at its cathode potential of +1.7, clamping positive pulses to the grid of  $V_5$  at +2.2 volts. These pulse amplitudes are too low to affect the triggers. Negative pulses are not affected by the dot control  $V_4R_6$ , but are grounded out by  $D_1R_{16}$ .

#### Dot Generation

When the output is to be a dot,  $V_{10}$  is made conductive by SMS action, establishing +10 volts at  $R_{24}$ . This effectively cuts off  $V_4$ , whose grid does not rise above +8 volts at  $R_{10}R_{11}$ . The first succeeding positive pulse from  $C_2R_4$ rises to +10 volts at the grid of  $V_5$  to transfer conduction to that tube. The resultant drop across  $R_8$  transmits a 60-volt negative pulse toward the grid of  $V_7$  via  $C_4$  and  $R_9$ . This cuts off  $V_7$  and transfers conduction to  $V_8$ . The junction  $R_{12}R_{13}$  stabilizes at -15 volts to cut off  $V_3$ , releasing the relay for marking output.

The following negative pulse cuts off  $V_5$  and returns conduction to  $V_6$ . As  $V_5$  cuts off, a positive pulse is transmitted via  $C_4$  to the grid of  $V_7$ , to return conduction to that tube. The junction of  $R_{12}$  and  $R_{13}$  returns to ground potential, and  $V_3$  pulls up the relay for spacing output.

Even if the key is held closed, with a constant +10 volts standing on  $R_{24}$ , the output cannot again go to marking until the next positive timing pulse, ensuring a full half cycle of spacing output to complete the dot.

#### Dash Generation

When the output is to be a dash,  $V_{11}$  is made conductive by SMS action, and +10 volts Conduction in  $V_8$  reduces the potential at  $R_{15}$  to +2.2 volts. The voltage at the junction of  $R_{10}$  and  $R_{11}$  drops to -0.5 to cut off  $V_4$ , whose cathode now stands at +0.9 volts. (The cut-off voltage is low because the plate voltage is only about 10 volts.)  $C_5R_{14}$  delays this drop until well after the first positive pulse has decayed at the grid of  $V_5$ . The second positive pulse can now trip  $V_5V_6$  to  $V_5$  conduction.  $V_8$  continues to conduct, of course. The second negative pulse cuts off  $V_5$ , which returns conduction to  $V_7$  and the output to spacing. The output cannot again go to marking until the next positive pulse, ensuring the half cycle of spacing to complete the dash after  $1\frac{1}{2}$  cycles of marking output.

When conduction is first transferred from  $V_7$  to  $V_8$ , a 19-volt negative pulse is transmitted from the grid of  $V_7$  toward the plate of  $V_5$  via  $C_4$ , but  $R_9$  limits it to insufficient amplitude to upset stable conduction in  $V_6$ . If SMS action has transferred sequencer conduction to  $V_{11}$  by the time of the second positive pulse in the dash, the elevation of the cathode of  $V_4$  is only incidental, since the drop at  $R_{10}R_{11}$  has already cut off  $V_4$ .

#### Automatic Spacing Characters

As in the relay model, interletter and interword spacing characters are obtained by allowing one or two positive pulses to go by. Closure of a key at any time following a passed-up positive pulse produces marking output beginning at the next positive pulse.

#### **Memory Actuation**

The dot-memory trigger  $V_{13}V_{14}$  idles with  $V_{13}$ conducting. This is the opposite tube of the pair from that in the code generators, facilitating the use of readily-derived positive memoryclearance pulses and a simple sequencing structure. While idle,  $C_{12}$  discharges and  $C_{13}$  charges through  $R_{31}$ . Closure of the dot key lifts the grid of  $V_{14}$  on charging current to  $C_{12}$  to the  $\pm 10$ -volt value standing at  $R_{37}R_{38}$ .  $C_{13}$  discharges immediately and ensures  $C_{12}$  action despite a possibly scratchy contact at the key. The comparatively slow (2 millisecond) charge rate of  $C_{13}$  through  $R_{31}$  prevents unwanted memory actuation from contact scratch as the key is released. The grid of  $V_{14}$  rises from -13 volts and stablizes at +10 volts with  $V_{14}$  conducting. The key may be immediately opened and the dot selection will be stored in the actuated trigger until cleared by appearance of the dot at the output.

# Memory Clearance

The dot memory is cleared under control of  $D_5R_{34}$  by a positive pulse to the grid of  $V_{13}$ ,

generated by  $C_{11}R_{36}$  from the  $V_3$  plate swing as the output goes to marking. To prevent spurious memory retrip,  $D_7$  grounds the negative pulse generated as the output goes to spacing.

Only one sequencor tube can conduct at a time. If the output character following the time of dot storage is to be a previously-selected dash,  $V_{11}$  conducts and only  $\pm 1.7$  volts stands at  $R_{24}$ . The clearance pulse toward the dot memory is clamped to that amplitude by  $D_5R_{34}$ , insufficient to clear the memory. When  $V_{10}$  is conductive for dot output, the pulse is allowed to rise to  $\pm 10$  volts at the grid of  $V_{13}$  and return conduction to  $V_{13}$  to clear the memory. The dash memory  $V_{15}V_{16}$  behaves identically, with clearance under the control of  $V_{11}D_6R_{35}$ .

# Sequence Interlock

When the dot memory is idle and the dot key is open, the junction of  $R_{30}$  and  $R_{32}$  applies -13 volts to the grid of  $V_{10}$ , via  $R_{21}$  and  $R_{31}$ , to cut off the tube. Tripping of the dot memory applies +10 volts from  $R_{30}R_{32}$  toward the grid of  $V_{10}$ . If  $V_{11}$  is being held conductive by a positive selection potential from the dash memory or key, its plate current through  $R_{18}$  lowers the potential at  $R_{19}R_{20}$  to -7 volts. The positive potential directed toward the grid of  $V_{10}$  by a dot selected under this condition is clamped by  $D_3R_{21}$ , and the grid of  $V_{10}$  is held below cut-off. This guarantees prior transmission of an earlier selected dash.  $C_7$  stabilizes the negative interlock voltage against spurious releases by plate voltage fluctuations caused by line-voltage changes and distributed capacitive couplings. This is necessary at very low line voltages, where the interlock potential drops to around -3 volts.

With the dash memory clear and the dash key open,  $V_{11}$  is cut off by -13 volts at  $R_{39}R_{40}$ , and  $R_{19}R_{20}$  stands at +12 volts. This allows the +10-volt dot selection potential to reach the grid of  $V_{10}$  via  $R_{21}$ . The cathode of  $V_{10}$ rises to +10 volts to start a dot on the next positive time-base pulse, and permits the memory clearance pulse to reach the grid of  $V_{13}$ . Conduction through  $V_{10}$  and  $R_{27}$  lowers  $R_{28}R_{29}$  to -7 volts, to clamp at  $D_4R_{25}$  any subsequently selected dash until after the dot starts. Additionally, by thus locking out  $V_{11}$  and holding  $R_{25}$  and the cathode of  $D_6$  at +0.9 volts, clearance of the dash memory (when actuated after dot storage but before that dot starts) is prevented.

For a series of dots, the key is held closed and +10 volts from  $R_{37} R_{38}$  holds  $V_{10}$  conductive via  $R_{21}$  (and  $V_{11}$  locked-out) after the dot memory clears at the start of the first dot, until the key is released or the sequencor is "seized" by subsequent actuation of the dash memory. The similar structure of the dash sequencor behaves identically under interlock control of the doth sequencor, to provide single or multiple dashes.

#### Sequence Transfer

Assume a dot and a dash, selected in that order before any output starts, and the keys (Continued on page 122)

# • Recent Equipment — The Sonar CD-2 Transmitter-Receiver

As its name implies, the Sonar CD-2 was designed especially for civil defense radio service. As one of the few v.h.f. amateurband pieces of gear presently approved by the Federal Civil Defense Administration for matching funds, it is of more than ordinary interest. To qualify for FCDA approval, v.h.f. equipment must comply with fairly stiff specifications as to frequency stability and selectivity.

Achieving the required stability in the transmitter was probably no great problem; crystal control and reasonable care in mechanical and electrical design take care of that. But adequate selectivity in a 2-meter receiver runs to some appreciable complication, and when selectivity is achieved, oscillator instability is likely to be something of a headache. A glance at the block diagram, Fig. 1, will show how these matters are handled in the CD-2.

The receiver uses ten tubes. The front end has a 6BK7 series cascode, for low noise figure, followed by a 6AK5 pentode. Self-tuned coupled circuits are used between the second half of the cascode and the 6AK5 grid, and between the 6AK5 plate and the first mixer. Coupling between these circuits is adjusted to give the desired flat response across the band, and the series of circuits gives reasonably high attenuation of signals outside that band. Oscillator stability is assured through the use of a voltage-regulated oscillator-doubler arrangement, with a self-tuned circuit in the doubler plate lead, and very light coupling between the oscillator and doubler.

Output from the first mixer is at 10.7 Mc., and there is one stage of i.f. amplification at this frequency. Then follows a 6U8 mixer-oscillator,

The Sonar CD-2 transmitter-receiver case is designed especially for civil defense station needs. The drop front has a plywood insert to make a writing surface. Space for log, message blanks, microphone cables and other accessories is provided, and the cover and front lock together to prevent unauthorized use.

the latter crystal-controlled, converting to 455 kc. Two stages of i.f. at 455 kc. work into a conventional diode-triode combination that performs the functions of detection, a.v.c., noise

limiting and audio amplification. The receiver ends up in a 6AQ5 power audio stage, where a choice of speaker, 'phones-withspeaker, or 'phones alone is afforded.

The transmitter line-up consists of a 12BY7 crystal oscillator-tripler, using 8-Mc. ervstals, a 6AK6 doubler, a pair of 6J6s in pushpull-parallel tripling, and a 6252 as a straight-through amplifier on 144 Mc. Inductively-coupled doubletuned circuits are used in the last three stages to provide essentially flat respouse across the band and good attenuation of unwanted oscillator-multiplier frequencies. The rated

Interior of the CD-2. Transmitter components are at the left; receiver and power supply on the right.

output of 17 watts seems quite conservative and is readily developed.

Modulation is supplied by a pair of 6AQ5s, driven by a 12AT7. A Type F1 carbon button microphone is used, and there is provision for either push-to-talk or toggle-switch control of the sendreceive operation. A small amount

mum of adjustment is required in normal operation. Alignment adjustments of both transmitter and receiver are preset, and should not require adjustment except in case of parts failure or other damage. In the case of the receiver,

of r.f. output is coupled off at the antenna connection to an r.f. voltmeter to provide for tuning up. Indication of transmitter tuning is shown on a meter, which doubles as a tuning meter for reception, and in addition there is a red jewel light that indicates both output and modulation. The circuit used for these purposes is reproduced in Fig. 2.

# Tuning & Adjustment

In keeping with its intended service, the CD-2 is designed so that a mini-

the operator merely turns the calibrated dial, and adjusts the audio level to suit conditions. Maximum downward swing of the meter indicates proper tuning of a signal.

The transmitter has provision for eight crystalcontrolled channels, selection being made with a single front-panel switch. The only tuning adjustments are the final plate tank and the antenna series-tuning capacitors. A front-panel "calibrate" switch applies screen voltage to the crystal oscillator, when the station is in the

Bottom view of the Sonar transmitter-receiver. Receiver and power supply occupy the large section. "receive" position, to permit checking the operating frequencies and the receiver calibration against each other. The harmonic from the crystal oscillator in the 144-Mc. band is strong enough to make an appreciable dip show on the tuning meter as the receiver is tuned across the operating frequency.

The CD-2 housing and accessories are designed for its rôle as a civil defense control station.

Fig. 2 — Tuning indicator circuit used for checking transmitter adjustments in the CD-2. In the complete circuit, the meter is also switched to indicate strength of the received signal.

The drop front and hinged top lock together with a cut key, so that unauthorized use can be prevented. The bottom portion of the case has ample space for log, message blanks, spare cables and other small accessories. The front cover has a large plywood insert, to provide a writing surface for field use. The cover can also be removed readily, to save space in a permanent installation. Carrying handles are provided on the sides of the case. The shelf on which the chassis rests is copper plated, to provide good contact with the chassis, and it is made of expanded metal for full ventilation. The front panel has a shaded desk light that can be turned on or off by a toggle switch.

The power supply works on either 6-volt d.c. or 115-volt a.c. input, separate cables being plugged into a single receptacle on the rear wall of the chassis. The socket is reached through a hinged door in the back of the cabinet. Selenium rectifiers are used, this being the first instance we've seen where they have been applied to amateur gear of this power rating. The result should be superior regulation, and an appreciable saving in drain when the rig is run from a 6-volt source. An operating check of the unit showed the total drain from a 6-volt storage battery to be 20 amperes on receiving and 33 on transmitting. Extended use with storage-battery power should not be attempted unless a satisfactory means of charging is at hand, as output drops rapidly after the first 5 minutes of use from a fully-charged battery.

The manufacturer supplies the CD-series gear for any 4.5-megacycle segment of the spectrum from 50 to 180 Mc., so a CD-6 is also available for use in the amateur 50-Mc. band. Both amateur band units may be expected to find considerable acceptance in areas where c.d. planning is well organized, and supported by local or state-wide governmental agencies. — E. P. T.

# The Gonset 6-Meter Communicator

**T**<sup>F</sup> lack of suitable ready-made gear has been a factor in the present rather low state of activity on the 6-meter band, here's a complete package that should go a long way toward injecting new life into what could be one of our most interesting slices of the r.f. spectrum. Certainly the 2-Meter Communicator has become one of the most familiar features of the v.h.f. scene. This has come about because it combines in one small convenient unit many features that make for pleasant and effective 2-meter work.

The new 6-meter model is physically an almost

exact duplicate of the popular 2-meter job. It is built, insofar as possible, around the same components and subassemblies that are used in the 2-meter rig, and it has the same useful gadgets. These include a tuning eye that works on both transmitter and receiver; a crystal spotter, for checking transmitter frequency and receiver calibration; an adjustable squelch, for quicting the receiver during stand-by periods; universal power supply, for both mobile and home-station use; the option of either carbon or crystal microphone input; provision for use of the audio system

The double-conversion receiver unit, left, and combined transmitter and audio system, right, are little more than good-sized handfuls.

The 6-Meter Communicator by Gonset is physically an exact duplicate of its 2-meter counterpart. Individual adjustment of all transmitter stages is made through holes in upper left side of the front panel, proper setting being indicated by closure of the tuning eye. Receiver has squelch-level, volume and noise limiter controls, lower left.

for public-address work; and many other features.

In addition, there are innovations that help the 6-Meter Communicator cope with conditions different in several respects from those encountered in 2-meter operation. The receiver is a double-conversion job, providing considerably better selectivity than the single-conversion 6-Mc. i.f. in the 2-meter receiver. The tuning range is extended one megacycle below the edge of the band, permitting monitoring of the mobile services in the 49-Mc. region for signs of band openings. Enough use of these frequencies is made in most parts of the country so that something will be heard almost any time that sporadic-E or  $F_2$ -layer skip is present. There is a built-in low-pass filter, connected permanently in the antenna lead, to reduce harmonics from the transmitter and spurious responses in the receiver.

For obvious manufacturing reasons, the transmitter has the same tube line-up as the 2-meter one, but there is one less multiplier stage. A 6CL6 crystal oscillator-multiplier, with either 8- or 12-Mc. crystals, drives a 12AV7 parallel doubler to 50 Mc. The final stage is a 2E26, delivering an output of about 6 watts. (We measured better than 6 watts with a Micromatch into a matched load.) The modulator has a 12AX7 amplifier working into a 6V6GT. This also serves as the receiver audio system.

The receiver front end has a 6BQ7A cascode r.f. amplifier and a 12AT7 mixer-oscillator, with 11-Mc. output. The receiver oscillator is on the high side, so there is no problem with 28-Mc. images. Mixer output is 11 Mc., and there is one stage of i.f. amplification, a 6BH6, at this frequency. Then follows a 6BE6 converter to 1500 kc., and a 6BJ6 i.f. amplifier. The functions of detector, noise limiter, a.v.c. rectifier and first audio amplifier are combined in a 6T8, which feeds the audio system. A subminiature 6BG7 dual triode handles the squelch. Our noise generator shows that the noise figure of the 6-Meter Communicator is better than is required for good weak-signal reception.

The power supply is identical to the 2-meter unit, having two 6X4 rectifiers, and provision for either 6-volt d.c. or 115-volt a.e. input. Connections for these two types of operation are made by separate cables supplied with the unit.

A variation from the 2-Meter Communicator is seen in the antenna furnished. The 19-inch whip is replaced by a polyethylene-insulated half-wave Zepp that can be rolled up and carried in a pocket. The quarter-wave whip idea is less effective with the 6-meter rig, as there is insufficient metallic mass in the cabinet to serve as a ground-plane at this lower frequency. The manufacturer also offers 6-Meter yagi antennas that can be used individually or in stacked pairs.

Cabinet appearance, power supply and audio system are identical to the 2-Meter Communicator. The 6-meter model is supplied for either 6- or 12-volt operation. -E. P. T.

Bottom views of the receiver and transmitter used in the 6-Meter Communicator. Outboard unit on back of receiver is cascode r.f. amplifier. Receiver and transmitter use common audio system.

41

## BOARD MEETING

In May the Board of Directors of the American Radio Relay League will meet to examine the record for 1954, and to come to decisions charting a continuing course for the future. The director of your division is your voice in League affairs. Communicate to him your views ou matters of the day so that he may be informed, as is required of him in the By-Laws, "as to conditions and activities in his territorial division and as to the needs and desires of the members therein in order that he may faithfully and intelligently represent the true interests of such members."

#### TECHNICIANS GET 50 MC.

In mid-March FCC released its decision in Docket No. 11157, dealing with Technician Class privileges: the 50-54 Me. band is opened to that class of license effective April 12th; FCC dismissed its proposal to open also the 144-Me. band to Technicians. The text of the order follows:

1. As a result of its consideration of petitions for rule making filed by James M. Price and Tom A. Walker, the Commission adopted the Notice of Proposed Rule Making in this proceeding, and it was published in the Federal Register on September 11, 1954, 19 FR 5917. The Notice proposed amendment of Section 12.23(d) to permit operation by Technician Class amateur operators in all amateur frequency bands above 50 Mc. which would have the effect of adding the 50-54 Mc. and the 144-148 Mc. bands to the privileges presently available to the Technician Class licensee. The petitions of Messrs. Price and Walker proposed addition only of the 50-54 Mc. band to the existing privileges for the Technician Class operator.

2. Comment on the proposed amendment was submitted by some 18 amateur organizations and over 125 amateurs individually. In regard to the 50-Mc, band, there appears to be substantial expression of approval of provision for Technician Class operator privileges therein.

3. As evidenced by the comment received, there appears to be considerable controversy as to whether technicians should be allowed to operate in the 144 Mc, band. Because of the opposition expressed by the American Radio Relay League, and because it does not find the arguments expressed in the comments otherwise decisive, the Commission is hereby dismissing that portion of the proposed amendment having to do with technician privileges in the 144 Mc, amateur frequency band.

4. This amendment is issued pursuant to authority contained in Sections 4(i) and 303(f), (g), and (r) of the Communications Act of 1934, as amended. IT IS OR-DERED, That effective 3:00 a.m., EST. April 12, 1955, Section 12.23(d) of Part 12, Rules Governing Amateur Radio Service, IS AMENDED as set forth in the attached Appendix.

FEDERAL COMMUNICATIONS COMMISSION Mary Jane Morris Secretary

Adopted: March 9, 1955 Released: March 10, 1955

#### APPENDIX

SECTION 12.23(d) OF PART 12, RULES GOVERNING AMATEUR RADIO SERVICE, IS AMENDED AS FOLLOWS:

(d) Technician Class. All authorized amateur privileges in the amateur frequency band 50-to-54 Mc, and in the amateur frequency bands above 220 Mc.

#### **QST ARTICLE AWARDS**

The Executive Committee has announced its selection of three outstanding articles which appeared in QST during 1954, and awarded the authors each prizes of \$300, \$200 and \$100. Single-sideband, as might be expected from its rapid development in 1954, was the subject for the No. 1 spot — the judges were unanimous in making the first award to Warren B. Bruene, WØTTK, for his November article, "Distortion in Single-Sideband Linear Amplifiers." A special, and hitherto untreated, phase of TVI ran a close second — the next award was to F. E. Ladd, W2IDZ, for his two-part article in June and July,

On March 19th, 200 VEs representing all of Canada met in Montreal to honor Canadian Director Alex Reid, VE2BE, who on December 31, 1954, became the first director to complete 25 years of continuous service on the ARRL Board of Directors. Amateurs from all parts of Canada joined to present Alex with a single-sideband exciter nnit and accessory gear, as a token of appreciation. Here (*l. to r.*) are: ARRL General Manager Budlong, W1BUD; Mrs. Gordon Lynn; Director Reid; Mrs. Reid; ARRL President Dosland, WØTSN.

"50 Mc. TVI - Its Causes and Cures." Antennas, as last year, provided the third subject the award going to William B. Wrigley, W4UCW, for his February article "Impedance Characteristics of Harmonic Antennas."

# CHAMBERS' 25TH

On March 6th, C. Vernon Chambers, QSTTechnical Assistant, became the seventh member of the present ARRL Hg. staff to reach the 25year mark.

"Vern" came to Hq. as an office boy, but the inevitable happened --- the bug bit, and he shortly became W1JEQ. His interest and developing ability made him a logical candidate for

WIJEO

lab work, and he turned out a number of pieces of gear for QST, with special attention to lowpower equipment for the beginner. He was associated with Ross Hull in the development of u.h.f. gear for the *Handbook* and carried that work to completion after Hull's untimely death. Vern then took over the ARRL Technical Information Service until World War II interrupted with both Army and civilian service in the field of guided missiles.

Chambers' postwar projects for both QST and the Handbook have included a goodly number of items at beginner level, but have ranged into many other fields as well - mobile gear, development of high-power r.f. chokes, and all sorts of general transmitting designs. His bandswitching rig in January 1954 QST brought more response from amateurs than perhaps any other article postwar.

When we use on Vern the old saw, "The second 25 years are the hardest," it isn't really funny: he has that much longer to go before reaching retirement age!

### **OPERATION IN GREENLAND**

For some months negotiations have been in process for the authorization of amateur operation in Greenland by U. S. citizens. Permission has now been granted, under an agreement with the Danish government, and the U.S. military

May 1955

is to issue detailed rules and regulations as well as issue call signs from the block KG1AA through KG1LZ.

# NOVICE TALKING BOOK

The Division for the Blind, Library of Congress, through the facilities of the American Foundation for the Blind, has produced a new Talking Book, "The Radio Amateur's Novice Examination, Questions and Answers." Excerpted from ARRL publications, and with code practice material especially written and taped by Hq., the package consists of eight 12-inch record sides. It is available to qualified blind readers through the 28 regional libraries in the usual manner (see list page 30, January 1953 QST). Thomas B. Hedges, W3QQS, assistant chief of the Division, contemplates expanding the Talking Book program to higher grades of amateur license if interest warrants.

# A.R.R.L. OSL BUREAU

The function of the ARRL QSL Bureau system is to facilitate delivery to amateurs in the United States, its possessions, and Canada of those QSL cards which arrive from amateur stations in other parts of the world. All you have to do is send your QSL manager (see list below) a stamped selfaddressed envelope about 414 by 91/2 inches in size, with your name and address in the usual place on the front of the envelope and your call printed in capital letters in the upper left-hand corner. (Bold-face type indicates change since last QST listing.)

- W1, K1 J. R. Baker, jr., W1JOJ, Box 232, Ipswich, Mass.
- W2, K2 H. W. Yahnel, W2SN, Lake Ave., Helmetta, N. J.
- W3, K3 Jesse Bieberman, W3KT, Box 34, Philadelphia 5, Penna.
- W4, K4 Thomas M. Moss, W4HYW, Box 644, Municipal Airport Branch, Atlanta, Ga.
- W5, K5- Oren B. Gambill, W5W1, 2514 N. Garrison. Tulsa 6, Okla.
- W6, K6-Horace R. Greer, W6TI, 414 Fairmount St., Oakland, Calif.

# **21st ARRL Sweepstakes Results**

# Part I - C.W.

BY PHIL SIMMONS, WIZDP

YAYS W5VNW: "Thanks for 40 hours of solid enjoyment. As the operator of a fixed, lowpower station, the Sweepstakes is my choice of all the contests." Says W1UTA: "I like the SS because it offers good practice in operating procedure, the thrill of raising new sections, an opportunity to learn how the rig really performs. but best of all, the chance to study the personality of a good cross-section of Hamdom. I have observed with a grin the leisurely fellow whose clock is five minutes slow, the hurry-hurry boy who doesn't wait for a 'roger,' and the operator who CQs 15 times before you find you've already worked him." Says WØBUR: "I like the absence of the cut-throat dog-cat-dog competition that marks some other contests." Says W4CVM: "Conditions were about as near perfect as I can remember them. There seemed to be more of the 'old ham spirit' this year, and all of the regulars were on hand: W3BES, W4IA, W9IOP, W1FTX, W4KFC, W4CIU and many others." Says W8APC: "Judging from the serial numbers

being sent the second week end, the entire population of the state of Connecticut will be needed to check the logs!"

The foregoing colorful contestimonials show why 1796 entrants (1394 c.w.) enjoyed themselves immensely (and why contest-checker W1CUT, ex-W5TQD, almost went back to Texas). [They indicate, too, why the 1954 SS

Jack Bryant, W5TFB, was stricken by SS-itis at an early age. Now 17, Jack already has stacked three consecutive North Texas wins, was tenth high nationally and top W5 in the '54 doings.

moves into the record books as the biggest ever held, dwarfing previous highs registered in 1939 and 1953. Griping about contest rules and poor conditions was all but nonexistent as scores rocketed to adding-machine proportions and 84 hard-working section and Novice winners earned certificates for brasspounding.

We're pleased to revive a popular prewar SS feature which listed, among other items, the equipment and bands of the section leaders. Aided by some fast slip-stick fumbling, one finds that there is real thought-food here; e.g.:

1) About 85 per cent of the 72 section winners utilized the trusted 20-40-80-meter band combination (although five of them scooped up extra credits on 15 meters).

2) Seventy-seven per cent fell in the 100-wattsor-less category, while the rest ran high power.

3) The average winner racked up 590 contacts in 66.6 sections for 97,450 points, was active 35 hours with 175 watts input.

4) Low-power champ was 25-watt Oklahoman W5WZV.

5) One-band champ was South Texan W5WQN with 704 QSOs on 7 Mc.

The set-ups in the tabulation typify the "new look" in SS circles, as compared with the May, 1940 QST version, which recorded such bottles as

.

Md.-Del.-D.C. leader W3JTK settled for 180,510 points, ranked fifth amongst the 1394 c.w. entrants with a 100 per cent home-brew rig. The gadget at the upper right, a photoelectric-keyed CQ SS wheel, gave a good account of itself, Jack reports.

# QST for

860s, T-40s, HK-254s and 211s in vogue in those days. (And you just can't hardly get them no more!) Riffle through your old-time QSTs and see for yourself what the previous generation of SS enthusiasts worked with.

by heart! Each sends code reminiscent of a W1AW Qualifying Run and sports a cleau, etherwrenching signal. Each salted away over 1100 contacts and attained, for the first time in SS annals, a final score in excess of 200,000 points. Congratulations are in order, then, to W4KVX

Now here's a foursome that knows the business

ł

### C.W. WINNERS, 21st A.R.R.L. SWEEPSTAKES CONTEST

May 1955

for his all-time record-smashing 209,353-point tally, and to W9IOP, W4KFC and W7KVU for their totals of 208,506, 203,850 and 202,210, respectively.

And for their savvy and downright stick-toit-iveness, plaudits and salaams to these others who broke 125.000; W3JTK 180.540, W7KEV 157,230. W3EIS 165,638, W9ERU 168.448. W9YFV 154,030, W5TFB 152,479, W3GHM W3FRY1 145,726, 147,502. W8LQA 146, 213,W8BTI 144,540, W9RQM 143,080, W6EPZ 141,468, 142.076. W5KC **W3AEL** 140,875, WØYCR 139.650, W3JBC 134,502, K6BLL<sup>1</sup> 133,590. W2SSC 133,175, WØTKX 133,043, W3CTJ 132,313,WØNWX 131,850, W9NPC 131,823, W3BES 130,488, W3GRF 130,315, K6CEF 130.123. W4PNK 129.634.W9PNE 129.330. W3JTC 128.845. W6HOC 127.294. W5ONZ 126.936. W7NLI 126.114.W8EV 125,925.

Section-hunting remains the favorite pastime of a goodly share of the gang, and it's quite an art. Here is the sharp-eared crew that bagged all 73 ARRL sections in '54: W1s EOB JTD ZDP. W2FEB, K2BZT, W38 ADZ ALB BES CTJ FRY JBC JNQ JTC KT, W48 KVX YFA, W5TFB, W6s BIP EPZ HOC MUR PYH ULS UTV YK, K6s BLL CEF, W7s GEB KEV KVU POE, W8s DUS EV, W9s IOP ROM YFV, WØTKX. Note that all U.S. licensing areas made the grade. Saskatchewan, Yukon/N.W.T. and Idaho would seem to be the toughies; 17 of the 37 experts named one of the three as the last section snagged. But K2BZT, who made the "clean sweep" in just 257 contacts, and ex-W1AW op W1JTD, who did it in 310, are the two who worked the *mostest* with the *leastest*. Choosy WØQDF likewise merits honorable mention for getting 72 out of a mere 74 QSOs.

Heartening indeed are the many friendly new faces that crop up yearly in the special Novice competition which the Sweepstakes affords. When three or more KN/WN people enter logs from a given section, the leader nabs an appropriatelyendorsed Novice certificate. The following yearlings earn a burst of applause, and the certificate as well, for graduating magna cum lande from their first venture into contest capers: WNIs BLD CDD, KN2HXR, WN3ZKH, WN5HIS, KN6EVR, WN8S SRK TGB, WN9s GBC HAH IGV, WN0SQE. See you in the '55 SS minus the "N," fellows!

# Sidelights

Lavish antenna systems were brought into play by the 200-grand quartet, W4KVX relied on 280- and 405-foot zepps, a 7-Mc. ground plane, and a 14-Mc. beam; all four were suspended from or mounted on telephone poles. W9IOP found an end-fed 136-foot wire, a 40-meter ground plane, and a 20-meter rotary to his liking; and so did W4KFC, who utilized an identical bunch of skyhooks. Out west, W7KVU made that huge signal even huger with such paraphernalia as (1) for 80 meters, a wire 12 wavelengths long and a half-wave zepp; (2) a 7-Mc. ground plane and zepp; (3) 3-element wide-spaced rotaries for 15 and 20. Lament from multiops W3x WIE WIF at close of festivities: "Brother, are we tired." (Boys, you weren't alone!) . . . W8CUP says his FL8A filter saved the day. . . . W2BRC got 43,935 and W2CJM 13,069 points with attic antennas. W2MUM pounded brass for the Order of BO (Boiled Owls). . . . Overheard on 20 the last Sunday: W1JYH

Budding contester Dick Brandt, KN2HXR, E. N. Y. Novice winner, got the most markers registered by a KN/WN in SS competition — over 10,000. For further news of Dick's operating sojourns, see the Novice Round-up results on page 50.

explaining the rules to W1KGH/VE8. After Rog had paved the way, the mob descended, . . . K2ENO broke in a new SX-24 and got 7 additional states. . . . Anchor man for Ohio Valley Amateur Radio Association was #-watt W8BAE ... Those who swapped messages with Iowan WØNWX unwittingly nailed FO8AJ/WØ. Bob was using the transmitter-inhaler combo of the famous Clipperton DXpedition (July, 1954, QST). . . . WØFVD is positive his code speed improved as a result of struggling with weak sigs in the QRM. . . . In '53 WN1YMA made 34 QSOs, in '54 W1YMA got 741! How's that for improvement! . . . W4LVV found conditions good except for one weird 90minute spell on 20 meters when it was impossible to raise anyone although incoming signals were strong. . . . W6OAY is confident QSLs will come through from several new states worked. . . . W3BQU/5 landed 23,490 points with a 24-watt transformerless rig. A voltage doubler juiced the p.p. 117L7s in the crystal oscillator circuit. Dimensions: a pocket-sized 4-by-4 inches. . . . KV4BK, ex-7CO (1912), 6RX (1920), and W5RX (1947), enjoyed the "other side of the fence" despite fierce QRM. QRT for 20 years, Charles

<sup>1</sup> Multioperator station.

#### NOVICE C.W. WINNERS, 21st A.R.R.L. SWEEPSTAKES CONTEST

| Section     | Call   | Scare  | Transmitter  | Watts Input | Receiver | Bands Used |

returned to top c.w. form rapidly in the SS. . . . Alaskan pace-setter KL7EVR apologizes for his difficult-to-read log transcribed at 16,000 feet during a KL7-to-W7 flight. . A 2-tube regen job performed the receiving chores for W6FAR. . . . W4KFC's 1183 stations worked in '53 is still tops. . . . With the same 30-watter he had last year us a Novice, W9YOS was tickled to multiply his score by 3. . W4KVX employed a card logging system complete with automatic time stamp and numbering machine to assist in avoiding or nullifying repeat QSOs as they occurred. . . W80TK thanks the boys for QRSing for him his first time out. . . . W7PQE got ten KL7s but had to cajole VE5 and KH6 non-SSers into swapping preambles. . . . Complete break-in system (March, 1954, QST) - using tubes for antenna-switching and receiver-quieting --- worked great at W7GEB. . . . We can thank W1RWP for increased Vermont activity. Stan has been carrying on a feverish one-man campaign to get better representation from that elusive section. . . . W4KMF/7 avows the competition in Arizona is considerably less rugged than it was in Virginia. . . . W5WZV captured his first SS scalp since 'way back in '36 and '37 when he earned Philippine honors as KAIUS. . . . WIWAI snared his 48th state, learned much about when to work which bands. . . . W11AP used a receiver-controlled VFO on 7 Mc. . . . W9RQM's XYL presented him with a new junior op during the SS. . . . The last 25-cycle power areas were being converted to 60 cycles near VE3ACB and intermittent power leaks held down his score. . . . W4KFC tells a little tale about a newlyrecruited Potomac Valley member, W4NQM, Sparkie was calling a Vermonter when his key actually fell apart, whereupon he scooped up a screwdriver, finished the call with the blade, and landed the Vermont station! . . . "My first SS in 19 years. The last time I entered, as W2BMX, I won for E.N.Y. with two crystals, 152 contacts. Needless to say, I was feeling my way in this one. Just wait 'til next year!'' -W4CXA... "What a wonderful time! The SS seems to get better every year. Conditions were the best that I can remember, and operating proficiency and signal quality were better than ever before. Chirps, yoops and clicks were at a low ebb, making operating a distinct pleasure. . . Some sort of award should be given to the XYLs who are the backbone of a good score. Where would we be without the hot coffee, special meals at off-hours, and plentiful supply of sharp pencils and log sheets. Yes, they describe a big hand for their help!" - W7KVU. ... "Surprised to end up with the same number of contacts (499) in 21st as in 20th SS. Also was lucky enough to have Vermont and VE8 reply to my CQ machine." — W6B1P. . . . "Wonderful contest! Found 21 Mc. wide open but nobody there; 14 Mc. hest hand out here." - W7GEB. . . . . "The 20-watt transmitter that gets RST 599 1000 miles away on 3.5-Mc. SS eye, when the customary handful of stations are tuning up for the event, is fairly ineffective in the melee starting at 1800 EST the next day, but 75 to 100 watts does the job FB. You can get the contacts with lower power but you have to work hard and be discouragingly patient. Every year, though, I'm back with more determination than ever. W8DM... "First contest and it was a barrel of fun." - W8IRO... "My object each year has been to work all sections. Thought I had it this time when a VE8 answered but discovered too late that I had missed Sacramento Valley. Oh well, maybe next year!" - W8ZJM. . Wow, what a battle! Heard the W6s working W1QMM (Vt.) on 20 but couldn't find him. My family is beginning to speak to me again!" - W3LMM. . . . "Gained valuable operating experience and learned how to tune up the rig in a hurry." - WØTLD. . . . "Conditions excellent the first session and almost as good the second. Sections I usually have trouble logging were in abundance, but there seemed to be a dearth of KZ5, VE5 and VE8 participants. This was my twelfth SS." - WØYCR. . . . "Bettered

With this spiffy layout, John Ryan, W7KVU, brought home a blistering 202,210 points and the Montana wallpaper. When he feels like creating additional db. for DX chasing, John uses the B & W 5100 to excite p.p. 4-400As at one kw.

May 1955

previous scores made as W3UVB and W8YJE and finally went over 100,000 points. No repeat contacts thanks to my first use of ARRL Operating Aid No. 6." --- W4CVI. . . . " My second SS and pleased to better last year's score considerably. A foolproof break-in system is a must!"-VE2CB.

Next month — be the good Lord willing! we'll bring you a symposium of club and 'phone highlights, including an A3 equipment tabulation and such photographs as we can muster. Di-dahdi-di-dit!

#### C. W. SCORES

#### Twenty-First Sweepstakes Contest

Scores are grouped by Divisions and Sections. . . . The operator of the station first-listed in each Section is award winner for that Section unless otherwise indicated. . . . Likewise the "power factor" used in computing points in each score is indicated by the letter A or B. . . . A indicates power up to and including 100 watts (multiplier of 1.25, c.w.), B over 100 watts (multiplier of 1). . . . The total operating time to the nearest hour, when given for each station, is the last figure following the score.... Example of listings: W3GHM 147,502-831-71-A-39, or, final score 147,502, number of stations 831, number of sections 71, power factor of 1.25, total operating time 39 hours. . . An asterisk denotes Novice certificate winners in sections where at least 3 Novice logs were submitted. . . . Multioperator stations are grouped in order of score following single-operator station listings in each section tabulation, with calls of participants in parentheses.
